## Introduction

This research memo should be seen as a first attempt to formulate an unified framework for the adjustment and testing of both the functional and stochastic models. In this memo we concentrate on the problem of estimating parts of the stochastic model. The unification is based on the method of least-squares. Our idea, which is worked out in this memo, was to investigate weather it is possible to use the method of least-squares adjustment also for the problem of variance component estimation. This turns out to be the case. As a consequence, we have the possibility of applying one estimation principle, namely our well-known and well understood method of least-squares, to both the problem of estimating the functional model and stochastic model.

Delft, 1988
The present document is a reprint of the original 1988 MGP-report 'Towards a Least-Squares Framework for Adjusting and Testing of both Functional and Stochastic Models'. Since the theory developed in this report is still considered to be relevant for many modern applications, it was decided to produce a more accessible format of the report. The original format turned out to be poorly reproducible electronically using modern day typesetting system. For the reprint we have chosen to use the popular $\mathrm{IA}_{\mathrm{E}} \mathrm{X}$ typesetting system. I am greatful to AliReza Amiri-Simkooei who took the painstaking task upon him to transform the original document into a $\mathrm{LA}_{\mathrm{E}} \mathrm{Xversion}$. This work is greatly acknowledged. To keep the flavor of the original report in tact (including its flaws), the current document is a complete one-to-one reprint of the original version. The current document is thus the ${ }^{I A} T_{E X}$ Xreprint of the original report.

Delft, 2004

## Chapter 1

## The Model: $\underline{y} \sim N\left(A x, Q_{y}\right)$

### 1.1 Linear Unbiased Estimators (LUE's)

Consider the linear model of observation equations:

$$
\begin{equation*}
E\{\underline{y}\}=A x, Q_{y} \tag{1.1}
\end{equation*}
$$

where $A$ is assumed to have full rank and the covariance matrix of $\underline{y}$ is assumed to be positive definite. Any linear unbiased estimator of $x$ can then be expressed as

$$
\begin{equation*}
\underline{\hat{x}}=\left(L^{*} A\right)^{-1} L^{*} \underline{y} \tag{1.2}
\end{equation*}
$$

where the $m \times n$ matrix $L$ is arbitrary provided that $\left(L^{*} A\right)^{-1}$ exists. The property of unbiasedness is easily verified with (1.1) and (1.2):

$$
\begin{equation*}
E\{\underline{\hat{x}}\}=\left(L^{*} A\right)^{-1} L^{*} E\{\underline{y}\}=\left(L^{*} A\right)^{-1} L^{*} A x=x \tag{1.3}
\end{equation*}
$$

The covariance matrix of $\underline{\hat{x}}, Q_{\hat{x}}$, follows from applying the error propagation law to (1.2):

$$
\begin{equation*}
Q_{\hat{x}}=\left(L^{*} A\right)^{-1} L^{*} Q_{y} L\left(A^{*} L\right)^{-1} \tag{1.4}
\end{equation*}
$$

The results (1.3) and (1.4) are independent of the distribution of $y$. Since the estimator $\underline{\hat{x}}$ of (1.2) is a linear estimator, it follows that if $\underline{y}$ is normally distributed then so is $\underline{\underline{x}}$. In this case, the distribution of $\underline{\underline{x}}$ is completely specified by its first two moments, i.e., $x$ and $Q_{\hat{x}}$.

### 1.2 Least-Squares Estimators (BLUE's)

Consider again model (1.1). The least squares (LSQ) estimator of $x$ reads then:

$$
\begin{equation*}
\underline{\hat{x}}=\left(A^{*} Q_{y}^{-1} A\right)^{-1} A^{*} Q_{y}^{-1} \underline{y}, \tag{1.5}
\end{equation*}
$$

Comparison of (1.2) with (1.5) shows that the least-squares estimator is a linear unbiased estimator. The corresponding choice for $L$ is:

$$
\begin{equation*}
L=Q_{y}^{-1} A \tag{1.6}
\end{equation*}
$$

substitution of (1.6) into (1.4) shows that the covariance matrix of the least-squares estimator reads

$$
\begin{equation*}
Q_{\hat{x}}=\left(A^{*} Q_{y}^{-1} A\right)^{-1} \tag{1.7}
\end{equation*}
$$

It can be shown that of all linear unbiased estimators, the LSQ-estimator has minimum variance. It is therefore a minimum variance linear unbiased estimator, also known in the literatures as BLUE (Best Linear Unbiased Estimator). This property of minimum variance is also independent of the distribution of $\underline{y}$.

## Chapter 2

## The Model: $\underline{y} \sim N\left(A x, \sum_{\alpha=1}^{p} \sigma_{\alpha}^{2} Q_{\alpha}\right)$

### 2.1 Least-Squares Estimation of $\sigma_{\alpha}^{2}, \alpha=1,2, \cdots, p$

Consider the linear model of observation equations:

$$
\begin{equation*}
E\{\underbrace{\underline{y}}_{m \times 1}\}=\underbrace{A}_{m \times n} \underbrace{x}_{n \times 1}, E\{\underbrace{(\underline{y}-A x)(\underline{y}-A x)^{*}}_{m \times m}\}=\sum_{\alpha=1}^{p} \sigma_{\alpha}^{2} \underbrace{Q_{\alpha}}_{m \times m} \tag{2.1}
\end{equation*}
$$

where $A$ is assumed to have full rank and the matrices $Q_{\alpha}$ are assumed to be non-negative definite such that the sum $\sum_{\alpha=1}^{p} \sigma_{\alpha}^{2} Q_{\alpha}$ is non-negative definite. Note that in this case, we have two sets of unknowns: the parameter vector $x$ and the variance components $\sigma_{\alpha}^{2}, \alpha=1,2, \ldots, p$. The idea of our least-squares approach to variance-component estimation is now to interpret the matrix equation of (2.1), which represents the covariance matrix of $\underline{y}$, as a set of $m^{2}$-number of observation equations. Thus, just like we interpret the functional model $E\{\underline{y}\}=A x$ as a set of $m$-number of observation equations with the observation vector $\underline{y}$, we are going to interpret the stochastic model $E\left\{(\underline{y}-A x)(\underline{y}-A x)^{*}\right\}=\sum_{\alpha=1}^{p} \sigma_{\alpha}^{2} Q_{\alpha}$ as a set of $m^{2}$-number of observation equations with the observation matrix $(\underline{y}-A x)(\underline{y}-A x)^{*}$. There is however one complication: the matrix $(\underline{y}-A x)(\underline{y}-A x)^{*}$ is not observable since the vector $x$ is unknown a-priori. This problem can however be circumvented by transforming model (2.1) into a model of condition equations. In terms of condition equations, model (2.1) reads

$$
\begin{equation*}
B^{*} E\{\underline{y}\}=0, E\left\{B^{*} \underline{y} \underline{y}^{*} B\right\}=\sum_{\alpha=1}^{p} \sigma_{\alpha}^{2} B^{*} Q_{\alpha} B \tag{2.2}
\end{equation*}
$$

where matrix $B$ satisfies

$$
\begin{equation*}
B^{*} A=0, \quad \text { with } \operatorname{rank}(B)=b \tag{2.3}
\end{equation*}
$$

Note that the unknown parameter vector $x$ has now been eliminated from the model. If we define the vector of misclosures, $\underline{t}$, as

$$
\begin{equation*}
B^{*} \underline{y}=\underline{t} \tag{2.4}
\end{equation*}
$$

We can write (2.2) more compactly as

$$
\begin{equation*}
E\{\underline{t}\}=0, \quad E\left\{\underline{t t}^{T}\right\}=\sum_{\alpha=1}^{p} \sigma_{\alpha}^{2} B^{*} Q_{\alpha} B \tag{2.5}
\end{equation*}
$$

Note that there is no adjustment needed for the first part, i.e., the functional part, of model (2.5). There is no redundancy and there are no unknowns. We may therefore concentrate on the second part, i.e., the stochastic part. The matrix equation of (2.5) can be recast into a set of $b^{2}$-number
of observation equations by stacking the $b$-number of $b \times 1$ column vectors of $E\left\{\underline{t t}^{T}\right\}$ into a $b^{2} \times 1$ observation vector. This results in the linear model of observation equations:

$$
E\{\underbrace{\left(\begin{array}{c}
\underline{t}_{1} \underline{\underline{t}}  \tag{2.6}\\
\underline{t}_{2} \underline{t} \\
\vdots \\
\underline{t}_{b} \underline{t}
\end{array}\right)}_{b^{2} \times 1}\}=\underbrace{\left(\begin{array}{ccc}
\left(B^{*} Q_{1} B\right)_{01} & \cdots & \left(B^{*} Q_{p} B\right)_{01} \\
\left(B^{*} Q_{1} B\right)_{02} & \cdots & \left(B^{*} Q_{p} B\right)_{02} \\
\vdots & \ddots & \vdots \\
\left(B^{*} Q_{1} B\right)_{0 b} & \cdots & \left(B^{*} Q_{p} B\right)_{0 b}
\end{array}\right)}_{b^{2} \times p} \underbrace{\left(\begin{array}{c}
\sigma_{1}^{2} \\
\sigma_{2}^{2} \\
\vdots \\
\sigma_{p}^{2}
\end{array}\right)}_{p \times 1}
$$

The notation $\left(B^{*} Q_{\alpha} B\right)_{01},\left(B^{*} Q_{\alpha} B\right)_{02}$, etc indicates the first, the second, etc column vector of the matrix $B^{*} Q_{\alpha} B$. If we denote the operator which transforms a matrix into a vector by vec, i.e.,

$$
\operatorname{vec}\left[\begin{array}{cccc}
x_{11} & x_{12} & \cdots & x_{1 n}  \tag{2.7}\\
x_{21} & x_{22} & \cdots & x_{2 n} \\
\vdots & \vdots & \ddots & \vdots \\
x_{n 1} & x_{n 2} & \cdots & x_{n n}
\end{array}\right]=\left[\begin{array}{ccccccccc}
x_{11} & \cdots & x_{n 1} & x_{12} & \cdots & x_{n 2} & \cdots & x_{1 n} & \cdots
\end{array} x_{n n}\right]^{*}
$$

Equation (2.6) can be written more compactly as

$$
E\left\{\operatorname{vec}\left(\underline{t t}^{*}\right)\right\}=\left[\begin{array}{llll}
\operatorname{vec}\left(B^{*} Q_{1} B\right) & \operatorname{vec}\left(B^{*} Q_{2} B\right) & \cdots & \operatorname{vec}\left(B^{*} Q_{p} B\right)
\end{array}\right]\left(\begin{array}{c}
\sigma_{1}^{2}  \tag{2.8}\\
\sigma_{2}^{2} \\
\vdots \\
\sigma_{p}^{2}
\end{array}\right)
$$

Having established this results, we can now apply the estimation methods of Section I. 1 and I.2. That is, we can now compute linear unbiased estimators of the variance components and also, if the covariance matrix of $\operatorname{vec}\left(\underline{t t}^{*}\right)$ is known, the least squares estimators (BLUE's) of the variance components. If we denote the covariance matrix of $v e c\left(\underline{t t^{*}}\right)$ by $Q_{v e c}$, the least-squares estimators of the variance components read:

$$
\left(\begin{array}{c}
\hat{\sigma}_{1}^{2}  \tag{2.9}\\
\hat{\sigma}_{2}^{2} \\
\vdots \\
\hat{\sigma}_{p}^{2}
\end{array}\right)=\left[\begin{array}{ccc}
n_{11} & \cdots & n_{1 p} \\
n_{21} & \cdots & n_{2 p} \\
\vdots & \ddots & \vdots \\
n_{p 1} & \cdots & n_{p p}
\end{array}\right]^{-1}\left[\begin{array}{c}
\operatorname{vec}\left(B^{*} Q_{1} B\right)^{*} Q_{v e c}^{-1} \operatorname{vec}\left(\underline{t t^{*}}\right) \\
\operatorname{vec}\left(B^{*} Q_{2} B\right)^{*} Q_{v e c}^{-1} \operatorname{vec}\left({\underline{t t^{*}}}^{*}\right) \\
\vdots \\
\operatorname{vec}\left(B^{*} Q_{p} B\right)^{*} Q_{v e c}^{-1} \operatorname{vec}\left({\underline{t t^{*}}}^{*}\right)
\end{array}\right]
$$

where

$$
\begin{equation*}
n_{k l}=\operatorname{vec}\left(B^{*} Q_{k} B\right)^{*} Q_{v e c}^{-1} \operatorname{vec}\left(B^{*} Q_{l} B\right), k, l=1,2, \cdots, p \tag{2.10}
\end{equation*}
$$

The above given least squares approach to variance component estimation has a number of attractive features:

1. Since the approach is based on the least squares principle, we know without any additional derivation that the estimators of (2.9) are unbiased and of minimum variance. These properties are independent of the distribution of $\operatorname{vec}\left(\underline{t t^{*}}\right)$. Note by the way that if $\underline{t}$ is normally distributed then $v e c\left(\underline{t t}^{*}\right)$ is certainly not normally distributed.
2. Since the approach is based on the least squares principle, the inverse of the normal matrix in (2.9) automatically gives us the covariance matrix of the variance components.
3. Since the approach is based on the least squares principle, parts of standard software can be used for computing the variance components.
4. Since the approach is based on the least squares principle, parts of our standard quality control theory (unfortunately only a few parts) can be applied to model (2.8) and the result (2.9).
5. The linear model of observation equations (2.8) makes it in principle rather straightforward to apply estimation methods other than least squares. One could in particular think of robust
estimation methods. This may turn out to be an important alternative if one wants to be guarded against misspecifications in the functional part of model (2.8).
In order to insure non negative variance components, one can also incorporate non-negativity constraints $\sigma_{\alpha}^{2} \geq 0, \alpha=1,2, \cdots, p$ in the model (2.8).
6. Finally, the least squares approach to variance component estimation is also attractive from a didactic point of view.

### 2.2 The Covariance Matrix of $\operatorname{vec}\left(\underline{t t^{*}}\right)$

In order to be able to compute the LSQ-estimators of the variance components in (2.9), we need to know the $b^{2} \times b^{2}$ covariance matrix of $v e c\left(\underline{t t}^{*}\right), Q_{v e c}$. In fact we need its inverse, $Q_{v e c}^{-1}$. In (2.9) we silently assumed that this inverse exist. It is however not difficult to show that the covariance matrix $Q_{v e c}$ is singular! Recall that

$$
\operatorname{vec}\left({\underline{t t^{*}}}^{*}\right)=\left(\begin{array}{c}
\underline{t}_{1} \underline{\underline{t}}  \tag{2.11}\\
\underline{t}_{2} \underline{\underline{t}} \\
\vdots \\
\underline{t}_{b} \underline{t}
\end{array}\right)
$$

Now define a $b^{2} \times 1$ vector as:

$$
a=\left[\begin{array}{c}
a_{1}  \tag{2.12}\\
a_{2} \\
\vdots \\
a_{b}
\end{array}\right]
$$

where $a_{i}, i=1,2, \cdots, b$ are vectors of order $b \times 1$. Taking the inner product of (2.11) and (2.12) gives

$$
a^{*} \operatorname{vec}\left(\underline{t}^{*}\right)=\sum_{i=1}^{b} \underline{t}_{i} a_{i}^{*} \underline{t}=\left[\begin{array}{lll}
\underline{t}_{1} & \cdots & \underline{t}_{b}
\end{array}\right]\left[\begin{array}{c}
a_{1}^{*} \underline{t}  \tag{2.13}\\
\vdots \\
a_{b}^{*} \underline{t}
\end{array}\right]=\underline{t}^{*}\left[\begin{array}{c}
a_{1}^{*} \\
\vdots \\
a_{b}^{*}
\end{array}\right] \underline{t}
$$

If we define

$$
A=\left[\begin{array}{c}
a_{1}^{*}  \tag{2.14}\\
\vdots \\
a_{b}^{*}
\end{array}\right]
$$

we have

$$
\begin{equation*}
a^{*} v e c\left(\underline{t t}^{*}\right)=\underline{t}^{*} A \underline{t} \tag{2.15}
\end{equation*}
$$

It will be clear that the covariance matrix of $v e c\left(\underline{t t}^{*}\right)$ is singular, if vector $a$ exist such that $a^{*} v e c\left(\underline{t t^{*}}\right)$ is zero. From (2.15) follows that such vectors indeed exist. For instance, if we take the $b \times b$ matrix $A$ to be skew-symmetric, i.e., $A^{*}=-A$, then

$$
\begin{equation*}
\underline{t}^{*} A \underline{t}=\left(\underline{t}^{*} A \underline{t}\right)^{*}=\underline{t}^{*} A^{*} \underline{t}=-\underline{t}^{*} A \underline{t} \tag{2.16}
\end{equation*}
$$

and thus ${ }^{1}$

$$
\begin{equation*}
a^{*} \operatorname{vec}\left(\underline{t t}^{*}\right)=0 \tag{2.17}
\end{equation*}
$$

It seems that the singularity of $Q_{v e c}$ makes things drastically more complicated. We will return to this matter in the next subsection. Let us however first derive the covariance matrix of vec $\left(\underline{t t^{*}}\right)$. The elements of the covariance matrix $Q_{v e c}$ are by definition given as

$$
\begin{equation*}
Q_{v e c}^{i j k l}=E\left\{\left(\underline{t}^{i} \underline{t}^{j}-E\left\{\underline{t}^{i} \underline{t}^{j}\right\}\right)\left(\underline{t}^{k} \underline{t}^{l}-E\left\{\underline{t}^{k} \underline{t}^{l}\right\}\right)\right\}, i, j, k, l=1,2, \cdots, b \tag{2.18}
\end{equation*}
$$

[^0]If we factor the right hand side we get

$$
\begin{equation*}
Q_{v e c}^{i j k l}=E\left\{\underline{t}^{i} \underline{t}^{j} \underline{t}^{k} \underline{t}^{l}\right\}-E\left\{\underline{t}^{i} \underline{t}^{j}\right\} E\left\{\underline{t}^{k} \underline{t}^{l}\right\}, i, j, k, l=1,2, \cdots, b \tag{2.19}
\end{equation*}
$$

This result shows that we need the second and the fourth multivariate central moments of the random vector $\underline{t}$. If we assume that $\underline{t}$ is normally distributed with mean zero and covariance matrix $Q_{t}$, the first four multivariate central moments read

$$
\begin{align*}
E\left\{\underline{t}^{i}\right\} & =0 \\
E\left\{\underline{t}^{i} \underline{t}^{j}\right\} & =q^{i j} \\
E\left\{\underline{t}^{j} \underline{t}^{j} \underline{t}^{k}\right\} & =0  \tag{2.20}\\
E\left\{\underline{t}^{i} \underline{t}^{j} \underline{t}^{k} \underline{t}^{l}\right\} & =q^{i j} q^{k l}+q^{i k} q^{j l}+q^{j k} q^{i l} \\
i, j, k, l & =1,2, \cdots, b
\end{align*}
$$

where $q^{i j}$ represents $Q_{t}$ in index notation. For a proof of (2.20) we refer to Appendix A. With (2.20), equation (2.19) can be written as

$$
\begin{equation*}
Q_{v e c}^{i j k l}=q^{i k} q^{j l}+q^{j k} q^{i l} \tag{2.21}
\end{equation*}
$$

From this results follows that the $b^{2} \times b^{2}$ covariance matrix $Q_{v e c}$ is composed of $b^{2}$-number $b \times b$ submatrices, i.e., as

$$
Q_{v e c}=\left(\begin{array}{cccc}
Q^{1.1 .} & Q^{1.2 .} & \cdots & Q^{1 . b .}  \tag{2.22}\\
Q^{2.1 .} & Q^{2.2 .} & \cdots & Q^{2 . b .} \\
\vdots & \vdots & Q^{i . k .} & \vdots \\
Q^{b .1 .} & Q^{b .2 .} & \cdots & Q^{b . b .}
\end{array}\right)
$$

where the $b \times b$ submatrix $Q^{i . k .}$ is of the form

$$
\begin{equation*}
Q^{i . k .}=e_{i}^{*} Q_{t} e_{k} Q_{t}+Q_{t} e_{k} e_{i}^{*} Q_{t} \tag{2.23}
\end{equation*}
$$

with $e_{i}^{*}=\left(\begin{array}{lllllll}0 & \cdots & 0 & 1 & 0 & \cdots & 0\end{array}\right)$.

### 2.3 The Singularity of $Q_{v e c}$ and Its Consequences

The covariance matrix $Q_{v e c}$ is singular if non-zero $b^{2} \times 1$ vectors $x$ exist such that

$$
\begin{equation*}
Q_{v e c} x=0 \tag{2.24}
\end{equation*}
$$

If we partition $x$ as

$$
x=\left(\begin{array}{c}
x_{1}  \tag{2.25}\\
x_{2} \\
\vdots \\
x_{b}
\end{array}\right)
$$

where $x_{k}, k=1,2, \cdots, b$ are $b \times 1$ vectors, we have with (2.23) that

$$
\begin{equation*}
\sum_{k=1}^{b} Q^{i . k .} x_{k}=\sum_{k=1}^{b}\left[e_{i}^{*} Q_{t} e_{k} Q_{t}+Q_{t} e_{k} e_{i}^{*} Q_{t}\right] x_{k} \tag{2.26}
\end{equation*}
$$

This can also be written as

$$
\sum_{k=1}^{b} Q^{i . k .} x_{k}=\left(\begin{array}{llll}
Q_{t} x_{1} & Q_{t} x_{2} & \cdots & Q_{t} x_{b}
\end{array}\right)\left[\begin{array}{c}
e_{i}^{*} Q_{t} e_{1}  \tag{2.27}\\
e_{i}^{*} Q_{t} e_{2} \\
\vdots \\
e_{i}^{*} Q_{t} e_{b}
\end{array}\right]+\sum_{k=1}^{b} Q_{t} e_{k}\left(e_{i}^{*} Q_{t} x_{k}\right)
$$

or as

$$
\sum_{k=1}^{b} Q^{i \cdot k} \cdot x_{k}=Q_{t}\left(\begin{array}{llll}
x_{1} & x_{2} & \cdots & x_{b}
\end{array}\right)\left[\begin{array}{c}
e_{1}^{*} Q_{t} e_{i}  \tag{2.28}\\
e_{2}^{*} Q_{t} e_{i} \\
\vdots \\
e_{b}^{*} Q_{t} e_{i}
\end{array}\right]+Q_{t}\left(\begin{array}{llll}
e_{1} & e_{2} & \cdots & e_{b}
\end{array}\right)\left[\begin{array}{c}
x_{1}^{*} Q_{t} e_{i} \\
x_{2}^{*} Q_{t} e_{i} \\
\vdots \\
x_{b}^{*} Q_{t} e_{i}
\end{array}\right]
$$

or as

$$
\sum_{k=1}^{b} Q^{i . k} x_{k}=Q_{t}\left(\begin{array}{llll}
x_{1} & x_{2} & \cdots & x_{b}
\end{array}\right)\left[\begin{array}{c}
e_{1}^{*}  \tag{2.29}\\
e_{2}^{*} \\
\vdots \\
e_{b}^{*}
\end{array}\right] Q_{t} e_{i}+Q_{t}\left(\begin{array}{llll}
e_{1} & e_{2} & \cdots & e_{b}
\end{array}\right)\left[\begin{array}{c}
x_{1}^{*} \\
x_{2}^{*} \\
\vdots \\
x_{b}^{*}
\end{array}\right] Q_{t} e_{i}
$$

or with

$$
X=\left(\begin{array}{llll}
x_{1} & x_{2} & \cdots & x_{b}
\end{array}\right) \text { and } I=\left(\begin{array}{llll}
e_{1} & e_{2} & \cdots & e_{b} \tag{2.30}
\end{array}\right)
$$

as

$$
\begin{equation*}
\sum_{k=1}^{b} Q^{i . k .} x_{k}=Q_{t} X Q_{t} e_{i}+Q_{t} X^{*} Q_{t} e_{i}^{*} \tag{2.31}
\end{equation*}
$$

or finally as

$$
\begin{equation*}
\sum_{k=1}^{b} Q^{i . k .} x_{k}=Q_{t}\left(X+X^{*}\right) Q_{t} e_{i}, i=1,2, \ldots, b \tag{2.32}
\end{equation*}
$$

This result shows that the vectors $x=\operatorname{vec}(X)$ which satisfy (2.24), are those vectors for which the matrix $X$ is skew-symmetric. These vectors therefore span the nullspace of the matrix $Q_{v e c}$. Now that we know the nullspace of the matrix $Q_{v e c}$, we can again start from model (2.8) to derive the least squares estimators. The fact that linear functions of the observations have zero variance, implies in general that the original linear model with singular covariance matrix can be reduced to a linear model with constraints and a non-singular covariance matrix. To see this, consider the linear model

$$
\begin{equation*}
E\{\underline{y}\}=A x, \quad Q_{y} \tag{2.33}
\end{equation*}
$$

If

$$
\begin{equation*}
T_{m \times m}=\binom{T_{1}}{T_{2}} \quad \text { with } \quad T_{1} T_{2}^{*}=0 \tag{2.34}
\end{equation*}
$$

is a square and regular transformation matrix, then model (2.33) is equivalent to

$$
E\left\{\left[\begin{array}{l}
T_{1} \underline{y}  \tag{2.35}\\
T_{2} \underline{y}
\end{array}\right]\right\}=\left[\begin{array}{l}
T_{1} A \\
T_{2} A
\end{array}\right] x, \quad\left[\begin{array}{ll}
T_{1} Q_{y} T_{1}^{*} & T_{1} Q_{y} T_{2}^{*} \\
T_{2} Q_{y} T_{1}^{*} & T_{2} Q_{y} T_{2}^{*}
\end{array}\right]
$$

If we assume that the row vectors of the matrix $T_{2}$ span the nullspace of $Q_{y}$, i.e., $Q_{y} T_{2}^{*}=0$, then (2.35) reduces to

$$
E\left\{\left[\begin{array}{l}
T_{1} \underline{y}  \tag{2.36}\\
T_{2} \underline{y}
\end{array}\right]\right\}=\left[\begin{array}{l}
T_{1} A \\
T_{2} A
\end{array}\right] x, \quad\left[\begin{array}{cc}
T_{1} Q_{y} T_{1}^{*} & 0 \\
0 & 0
\end{array}\right]
$$

And this model is indeed of the form of observation equations with constraints on the unknown parameter vector $x$. It thus seems that for our variance-component estimation problem we are dealing with a model of the form of (2.36). A closer look at our problem shows however that this is only part of the story! Let us go back to the $b^{2} \times 1$ vector $x$ that span the nullspace of the covariance matrix $Q_{v e c}$. We know from (2.32) that these vectors are characterized by

$$
\begin{equation*}
Q_{v e c} \operatorname{vec}(X)=0 \quad \text { with } \quad X^{*}=-X \tag{2.37}
\end{equation*}
$$

These vectors are in the formulation of (2.36) the row vectors of the matrix $T_{2}$. In (2.36) we need to compute the matrix $T_{2} A$. For our variance-component estimation model (2.8) this means that we need to compute the inner products of $\operatorname{vec}(X)$ with $\operatorname{vec}\left(B^{*} Q_{\alpha} B\right), \alpha=1,2, \ldots, p$. Thus $\operatorname{vec}(X)^{*} \operatorname{vec}\left(B^{*} Q_{\alpha} B\right), \alpha=1,2, \ldots, p$. Since

$$
\begin{equation*}
\operatorname{vec}(X)^{*} \operatorname{vec}\left(B^{*} Q_{\alpha} B\right)=\sum_{i=1}^{b} x_{i}^{*}\left(B^{*} Q_{\alpha} B\right)_{0 i} \tag{2.38}
\end{equation*}
$$

it follows that

$$
\begin{equation*}
\operatorname{vec}(X)^{*} \operatorname{vec}\left(B^{*} Q_{\alpha} B\right)=\operatorname{trace}\left(X^{*} B^{*} Q_{\alpha} B\right) \tag{2.39}
\end{equation*}
$$

Using the following two properties of the trace operator,

$$
\begin{equation*}
\operatorname{trace}(A B)=\operatorname{trace}(B A), \quad \text { and } \operatorname{trace}(A)=\operatorname{trace}\left(A^{*}\right) \tag{2.40}
\end{equation*}
$$

it follows that

$$
\begin{align*}
& \operatorname{trace}\left(X^{*} B^{*} Q_{\alpha} B\right)= \operatorname{trace}\left(B^{*} Q_{\alpha} B X^{*}\right) \\
&=\operatorname{trace}\left[\left(B^{*} Q_{\alpha} B X^{*}\right)^{*}\right]  \tag{2.41}\\
& \operatorname{trace}\left(X B^{*} Q_{\alpha} B\right)
\end{align*}=-\operatorname{trace}\left(X^{*} B^{*} Q_{\alpha} B\right) .
$$

Hence, with (2.39) we find that

$$
\begin{equation*}
\operatorname{vec}(X)^{*} \operatorname{vec}\left(B^{*} Q_{\alpha} B\right)=0, \quad \text { if } X^{*}=-X \tag{2.42}
\end{equation*}
$$

This is an important results, because it implies in the formulation of (2.36) that $T_{2} A=0$. With $T_{2} A=0$, model (2.36) reduces to

$$
\begin{equation*}
E\left\{T_{1} \underline{y}\right\}=T_{1} A x, \quad T_{1} Q_{y} T_{1}^{*} \tag{2.43}
\end{equation*}
$$

which is considerably simpler to solve than model (2.36). In our variance-component estimation problem we are thus in fact dealing with a model of the form (2.43). The least-squares estimator of $x$ in model (2.43) reads:

$$
\begin{equation*}
\underline{\hat{x}}=\left[A^{*} T_{1}^{*}\left(T_{1} Q_{y} T_{1}^{*}\right)^{-1} T_{1} A\right]^{-1} A^{*} T_{1}^{*}\left(T_{1} Q_{y} T_{1}^{*}\right)^{-1} T_{1} \underline{y} \tag{2.44}
\end{equation*}
$$

In our variance-component estimation problem matrix $Q_{v e c}$ takes the place of $Q_{y}$ of (2.44) and the rows of the matrix $T_{2}$ are given by a linear independent set of vectors $v e c(X)$ for which $X^{*}=-X$. Since we assumed that $T_{1} T_{2}^{*}=0$, the rows of matrix $T_{1}$ are given by a linear independent set of vectors $\operatorname{vec}(S)$ for which $S=S^{*}$. This follows from the fact that $\operatorname{vec}(S)^{*} \operatorname{vec}(X)=0$ if $S=S^{*}$ and $X^{*}=-X$ (Confer also (2.42). Since the subspace spanned by the vectors vec $(X)$ for which $X^{*}=-X$ has dimension $b(b-1) / 2$ if $X$ is of order $b \times b$, it follows that the dimension of the subspace spanned by the vectors $\operatorname{vec}(S)$ for which $S=S^{*}$ is given by $b(b+1) / 2$ if $S$ is of order $b \times b$. Thus, in our variance-component estimation problem the matrix $T_{1}$ of (2.44) is of order $b(b+1) / 2 \times b^{2}$. The matrix to be inverted, $T_{1} Q_{y} T_{1}^{*}$, is therefore of order $b(b+1) / 2 \times b(b+1) / 2$.

We will now show how, without explicitly inverting the matrix $T_{1} Q_{y} T_{1}^{*}$, the matrix $A^{*} T_{1}^{*}$ $\left(T_{1} Q_{y} T_{1}^{*}\right)^{-1} T_{1} A$ and the vector $A^{*} T_{1}^{*}\left(T_{1} Q_{y} T_{1}^{*}\right)^{-1} T_{1} \underline{y}$ of (2.44) can be computed. Consider the system of linear equations:

$$
\begin{equation*}
Q_{y} u=v \tag{2.45}
\end{equation*}
$$

We will assume that the system is consistent, i.e., that

$$
\begin{equation*}
v \in R\left(Q_{y}\right)=\text { range- or column-space of } Q_{y} \tag{2.46}
\end{equation*}
$$

If we reparameterize $u$ as

$$
\begin{equation*}
u=T_{1}^{*} \alpha+T_{2}^{*} \beta \tag{2.47}
\end{equation*}
$$

and substitute into (2.45) we get

$$
\begin{equation*}
Q_{y} T_{1}^{*} \alpha=v \tag{2.48}
\end{equation*}
$$

since $Q_{y} T_{2}^{*}=0$. Premultiplying (2.48) with $T_{1}$ and inverting the results gives

$$
\begin{equation*}
\alpha=\left(T_{1} Q_{y} T_{1}^{*}\right)^{-1} T_{1} v \tag{2.49}
\end{equation*}
$$

Substitution into (2.47) gives then

$$
\begin{equation*}
u=T_{1}^{*}\left(T_{1} Q_{y} T_{1}^{*}\right)^{-1} T_{1} v+T_{2}^{*} \beta \tag{2.50}
\end{equation*}
$$

This is the general solution of the consistent system (2.45). The first part on the right hand side of (2.50) represents a particular solution of (2.45) and the second part represents the homogeneous solution, i.e., the solution of $Q_{y} u=0$. When we premultiply (2.50) with $A^{*}$, the homogeneous part disappears since $A^{*} T_{2}^{*}=0$ and we get

$$
\begin{equation*}
A^{*} u=A^{*} T_{1}^{*}\left(T_{1} Q_{y} T_{1}^{*}\right)^{-1} T_{1} v \tag{2.51}
\end{equation*}
$$

From this result we can conclude that any particular solution (2.45) when premultiplied with $A^{*}$, equals the righthand side of (2.51). This implies that if we are allowed to take $v$ as one of the column vectors of $A$, say the $i^{t h}$ column vector, then the $i^{t h}$ column vector of $A^{*} T_{1}^{*}\left(T_{1} Q_{y} T_{1}^{*}\right)^{-1} T_{1} A$ is obtained from premultiplying an arbitrary particular solution of (2.45) with $v=A e_{i}$ by $A^{*}$. Similarly, if we are allowed to take $v$ equal to $\underline{y}$, then $A^{*} T_{1}^{*}\left(T_{1} Q_{y} T_{1}^{*}\right)^{-1} T_{1} \underline{y}$ is obtained from premultiplying an arbitrary particular solution of $(2.45)$ with $v=\underline{y}$ by $A^{*}$. What remains to be shown is therefore whether $R(A) \subset R\left(Q_{y}\right)$ and $\underline{y} \in R\left(Q_{y}\right)$. We will first proof $R(A) \subset R\left(Q_{y}\right)$. If $v \in R(A)$ then $v$ can be written as $v=A \lambda$ for some $\lambda$. Since $T_{2} A=0$ it follows that $T_{2} v=0$. Since $T$ is square and regular, and $T_{1} T_{2}^{*}=0$ it follows that $v=T_{1}^{*} \delta$ for some $\delta$. In order to continue our proof we first proof that

$$
\begin{equation*}
Q_{y}=T_{1}^{*}\left(T_{1} T_{1}^{*}\right)^{-1} T_{1} Q_{y} T_{1}^{*}\left(T_{1} T_{1}^{*}\right)^{-1} T_{1} \tag{2.52}
\end{equation*}
$$

clearly

$$
\begin{equation*}
Q_{y}=T^{*} T^{-*} Q_{y} T^{-1} T \tag{2.53}
\end{equation*}
$$

with

$$
T^{-1}=\left[\begin{array}{c}
\left(T_{1} T_{1}^{*}\right)^{-1} T_{1}  \tag{2.54}\\
\left(T_{2} T_{2}^{*}\right)^{-1} T_{2}
\end{array}\right]^{*}
$$

this gives

$$
Q_{y}=T^{*}\left[\begin{array}{cc}
\left(T_{1} T_{1}^{*}\right)^{-1} T_{1} Q_{y} T_{1}^{*}\left(T_{1} T_{1}^{*}\right)^{-1} & 0  \tag{2.55}\\
0 & 0
\end{array}\right] T
$$

Since $Q_{y} T_{2}^{*}=0$, from (2.55) equation (2.52) follows. We now know that if $v \in R(A)$ then $v=T_{1}^{*} \delta$ for some $\delta$. But with (2.52) this implies that $v \in R\left(Q_{y}\right)$. We have therefore shown that indeed $R(A) \subset R\left(Q_{y}\right)$. The proof that $\underline{y} \in R\left(Q_{y}\right)$ goes along the same line. We know from (2.43) that $T_{2} \underline{y}=0=$ constant. Therefore $\underline{y}=T_{1}^{*} \delta$ for some $\delta$. And again with (2.52) this implies that $\underline{y} \in R\left(Q_{y}\right)$.

We are now ready to apply the above to our problem of variance-component estimation. That is, in analogy with (2.45) we consider the consistent system

$$
\begin{equation*}
Q_{v e c} v e c(U)=\operatorname{vec}(V) \tag{2.56}
\end{equation*}
$$

where $V$ is chosen as (see (2.8))

$$
\begin{equation*}
V=B^{*} Q_{\alpha} B, \quad \alpha=1,2, \ldots, p \text { and } V=\underline{t t}^{*} \tag{2.57}
\end{equation*}
$$

According to (2.32) we can write $Q_{v e c} v e c\left(U_{\alpha}\right)=\operatorname{vec}\left(B^{*} Q_{\alpha} B\right)$ as

$$
\begin{equation*}
Q_{t}\left(U_{\alpha}+U_{\alpha}^{*}\right) Q_{t} e_{i}=B^{*} Q_{\alpha} B e_{i}, \quad i=1,2, \ldots, b \tag{2.58}
\end{equation*}
$$

or as

$$
\begin{equation*}
Q_{t}\left(U_{\alpha}+U_{\alpha}^{*}\right) Q_{t}=B^{*} Q_{\alpha} B \tag{2.59}
\end{equation*}
$$

or as

$$
\begin{equation*}
U_{\alpha}+U_{\alpha}^{*}=Q_{t}^{-1} B^{*} Q_{\alpha} B Q_{t}^{-1} \tag{2.60}
\end{equation*}
$$

From our previous discussion we know that any particular solution may be taken. One such particular solution is

$$
\begin{equation*}
U_{\alpha}=\frac{1}{2} Q_{t}^{-1} B^{*} Q_{\alpha} B Q_{t}^{-1} \tag{2.61}
\end{equation*}
$$

The $(\beta, \alpha)$-element of the normal matrix of our LSQ-solution of the variance-component estimation problem reads therefore

$$
\begin{equation*}
\operatorname{vec}\left(B^{*} Q_{\beta} B\right)^{*} \operatorname{vec}\left(U_{\alpha}\right)=\frac{1}{2} \operatorname{vec}\left(B^{*} Q_{\beta} B\right)^{*} \operatorname{vec}\left(Q_{t}^{-1} B^{*} Q_{\alpha} B Q_{t}^{-1}\right) \tag{2.62}
\end{equation*}
$$

If we denote this element as $n_{\beta \alpha}$ we have

$$
\begin{align*}
n_{\beta \alpha} & =\frac{1}{2} \operatorname{vec}\left(B^{*} Q_{\beta} B\right)^{*} \operatorname{vec}\left(Q_{t}^{-1} B^{*} Q_{\alpha} B Q_{t}^{-1}\right) \\
& =\frac{1}{2} \operatorname{trace}\left(B^{*} Q_{\beta} B Q_{t}^{-1} B^{*} Q_{\alpha} B Q_{t}^{-1}\right) \tag{2.63}
\end{align*}
$$

In a similar way as above we can write $Q_{v e c} v e c(U)=v e c\left(\underline{t t}^{*}\right)$ with the help of (2.32) as

$$
\begin{equation*}
U+U^{*}=Q_{t}^{-1} \underline{t t^{*}} Q_{t}^{-1} \tag{2.64}
\end{equation*}
$$

One particular solution is

$$
\begin{equation*}
U=\frac{1}{2} Q_{t}^{-1}{\underline{t t^{*}}}^{*} Q_{t}^{-1} \tag{2.65}
\end{equation*}
$$

Therefore

$$
\begin{equation*}
\operatorname{vec}\left(B^{*} Q_{\beta} B\right)^{*} \operatorname{vec}(U)=\frac{1}{2} \operatorname{vec}\left(B^{*} Q_{\beta} B\right)^{*} \operatorname{vec}\left(Q_{t}^{-1} \underline{t t^{*}} Q_{t}^{-1}\right) \tag{2.66}
\end{equation*}
$$

If we denote this element as $\underline{l}_{\beta}$ we have

$$
\begin{align*}
\underline{l}_{\beta} & =\frac{1}{2} \operatorname{vec}\left(B^{*} Q_{\beta} B\right)^{*} \operatorname{vec}\left(Q_{t}^{-1} \underline{t t^{*}} Q_{t}^{-1}\right) \\
& =\frac{1}{2} \operatorname{trace}\left(B^{*} Q_{\beta} B Q_{t}^{-1} \underline{t t}^{*} B Q_{t}^{-1}\right) \\
& =\frac{1}{2} \operatorname{trace}\left(\underline{t}^{*} Q_{t}^{-1} B^{*} Q_{\beta} B Q_{t}^{-1} \underline{t}\right)  \tag{2.67}\\
& =\frac{1}{2} \underline{t}^{*} Q_{t}^{-1} B^{*} Q_{\beta} B Q_{t}^{-1} \underline{t}
\end{align*}
$$

With (2.63) and (2.68) we are now able to compute the least-squares solution of the linear model (2.8) as:

$$
\left(\begin{array}{c}
\hat{\sigma}_{1}^{2}  \tag{2.68}\\
\hat{\hat{\sigma}}_{2}^{2} \\
\vdots \\
\hat{\sigma}_{p}^{2}
\end{array}\right)=\left[\begin{array}{ccc}
n_{11} & \cdots & n_{1 p} \\
n_{21} & \cdots & n_{2 p} \\
\vdots & \ddots & \vdots \\
n_{p 1} & \cdots & n_{p p}
\end{array}\right]^{-1}\left[\begin{array}{c}
\frac{1}{2} \underline{t} Q_{t}^{-1} B^{*} Q_{1} B Q_{t}^{-1} \underline{t} \\
\frac{1}{2} t^{*} Q_{t}^{-1} B^{*} Q_{2} B Q_{t}^{-1} \underline{t} \\
\vdots \\
\frac{1}{2} \underline{t}^{*} Q_{t}^{-1} B^{*} Q_{p} B Q_{t}^{-1} \underline{t}
\end{array}\right]
$$

with

$$
\begin{equation*}
n_{k l}=\frac{1}{2} \operatorname{trace}\left(B^{*} Q_{k} B Q_{t}^{-1} B^{*} Q_{l} B Q_{t}^{-1}\right) \tag{2.69}
\end{equation*}
$$

This solution thus replaces (2.9) where it was assumed that $Q_{v e c}$ was invertible. Note that while we took care of the singularity of $Q_{v e c}$, we also reduced the order of the matrices which need to be inverted. In (2.9) we had to invert an $b^{2} \times b^{2}$ matrix $Q_{v e c}$, while in (2.68) we have to invert
the $b \times b$ matrix $Q_{t}$. It should also be noted that, since we assumed $\underline{t}$ to be normally distributed when deriving the covariance matrix $Q_{v e c}$, the BLUE's property of (2.68) is restricted to the class of normal distributions. The LUE's property of course still holds in general. Finally we note that while the inverse of the normal matrix gives the covariance matrix of the variance-components, the normal matrix itself is the covariance matrix of the $p \times 1$ vector on the right hand side of (2.68).

Solution (2.68) can be used directly if the matrix $B$ is available. In practice however one will usually have the design matrix $A$ available, instead of $B$. We shall therefore have to rewrite (2.68) in terms of $A$. From (2.63) follows that

$$
\begin{equation*}
n_{\beta \alpha}=\frac{1}{2} \operatorname{trace}\left(B^{*} Q_{\beta} B Q_{t}^{-1} B^{*} Q_{\alpha} B Q_{t}^{-1}\right)=\frac{1}{2} \operatorname{trace}\left(Q_{\beta} B Q_{t}^{-1} B^{*} Q_{\alpha} B Q_{t}^{-1} B^{*}\right) \tag{2.70}
\end{equation*}
$$

with

$$
\begin{equation*}
Q_{y} B Q_{t}^{-1} B^{*}=I-A\left(A^{*} Q_{y}^{-1} A\right)^{-1} A^{*} Q_{y}^{-1}=P_{A}^{\perp} \tag{2.71}
\end{equation*}
$$

follows therefore

$$
\begin{equation*}
n_{\beta \alpha}=\frac{1}{2} \operatorname{trace}\left(Q_{\beta} Q_{y}^{-1} P_{A}^{\perp} Q_{\alpha} Q_{y}^{-1} P_{A}^{\perp}\right) \tag{2.72}
\end{equation*}
$$

Similarly, it follows with

$$
\begin{equation*}
\underline{\hat{e}}=Q_{y} B Q_{t}^{-1} B^{*} \underline{y}=Q_{y} B Q_{t}^{-1} \underline{t}=P_{A}^{\perp} \underline{y} \tag{2.73}
\end{equation*}
$$

from (2.68) that

$$
\begin{equation*}
\underline{l}_{\beta}=\frac{1}{2} \underline{\hat{e}}^{*} Q_{y}^{-1} Q_{\beta} Q_{y}^{-1} \underline{\hat{e}}=\frac{1}{2} \underline{y}^{*} P_{A}^{\perp} Q_{y}^{-1} Q_{\beta} Q_{y}^{-1} P_{A}^{\perp} \underline{y} \tag{2.74}
\end{equation*}
$$

As we mentioned earlier, (2.72) is the covariance matrix of (2.74). With (2.72) and (2.74), solution (2.68) can also be written as

$$
\left(\begin{array}{c}
\hat{\sigma}_{1}^{2}  \tag{2.75}\\
\hat{\sigma}_{2}^{2} \\
\vdots \\
\hat{\sigma}_{p}^{2}
\end{array}\right)=\left[\begin{array}{ccc}
n_{11} & \cdots & n_{1 p} \\
n_{21} & \cdots & n_{2 p} \\
\vdots & \ddots & \vdots \\
n_{p 1} & \cdots & n_{p p}
\end{array}\right]^{-1}\left[\begin{array}{c}
\frac{1}{2} \hat{e}^{*} Q_{y}^{-1} Q_{1} Q_{y}^{-1} \frac{\hat{e}}{\hat{e}} \\
\frac{1}{2} \hat{e}^{*} Q_{y}^{-1} Q_{2} Q_{y}^{-1} \underline{e} \\
\vdots \\
\frac{1}{2} \underline{e}^{*} Q_{y}^{-1} Q_{p} Q_{y}^{-1} \underline{\underline{e}}
\end{array}\right]
$$

with

$$
\begin{equation*}
n_{\beta \alpha}=\frac{1}{2} \operatorname{trace}\left(Q_{\beta} Q_{y}^{-1} P_{A}^{\perp} Q_{\alpha} Q_{y}^{-1} P_{A}^{\perp}\right) \tag{2.76}
\end{equation*}
$$

Let us as a simple application of (2.75), assume that there is only one variance component, i.e., $p=1$. From (2.75) follows then

$$
\begin{equation*}
\hat{\hat{\sigma}}^{2}=\frac{\frac{1}{2} \underline{\hat{e}}^{*} Q_{y}^{-1} Q_{1} Q_{y}^{-1} \underline{\hat{e}}}{\frac{1}{2} \operatorname{trace}\left(Q_{1} Q_{y}^{-1} P_{A}^{\perp} Q_{1} Q_{y}^{-1} P_{A}^{\perp}\right)} \tag{2.77}
\end{equation*}
$$

with

$$
\begin{equation*}
E\left\{\hat{\underline{\sigma}}_{1}^{2}\right\}=\sigma_{1}^{2} \quad \text { and } \quad \sigma_{\hat{\sigma}_{1}^{2}}^{2}=\frac{2}{\operatorname{trace}\left(Q_{1} Q_{y}^{-1} P_{A}^{\perp} Q_{1} Q_{y}^{-1} P_{A}^{\perp}\right)} \tag{2.78}
\end{equation*}
$$

with $Q_{y}=\sigma_{1}^{2} Q_{1}, P_{A}^{\perp} P_{A}^{\perp}=P_{A}^{\perp}$, and $\operatorname{trace}\left(P_{A}^{\perp}\right)=\operatorname{rank}\left(P_{A}^{\perp}\right)=m-n$, the above simplifies to:

$$
\begin{equation*}
\hat{\underline{\sigma}}_{1}^{2}=\frac{\hat{e}^{*} Q_{1}^{-1} \underline{\underline{e}}}{m-n}, \quad E\left\{\underline{\hat{\sigma}}_{1}^{2}\right\}=\sigma_{1}^{2} \quad \text { and } \quad \sigma_{\hat{\sigma}_{1}^{2}}^{2}=\frac{2 \sigma_{1}^{4}}{m-n} \tag{2.79}
\end{equation*}
$$

These are the well-known results for the estimator of the variance factor of unit weight. Our leastsquares approach implies that the above estimator is optimal in the sense that it is unbiased and has minimum variance! With our least-squares approach we now also have a unified framework in which the well-known estimator of the variance-factor of unit weight finds its logical place. That is, contrary to most lecture notes, we now do not have to introduce the estimator of the variance factor of unit weight in an ad hoc way!

### 2.4 Estimation of the Covariance Matrix from Repeated Measurements

In our least-squares approach we so far considered only the estimation of the variance-components $\sigma_{\alpha}^{2}$ of $Q_{y}=\sum_{\alpha=1}^{p} \sigma_{\alpha}^{2} Q_{\alpha}$. The whole procedure applies however equally well to the estimation of covariance components. In fact, the least squares approach can also be used to estimate the covariance matrix from repeated measurements.

From our formulae (2.68) and (2.75) we see that we need $Q_{y}=\sum_{\alpha=1}^{p} \sigma_{\alpha}^{2} Q_{\alpha}$ in order to compute the estimators $\hat{\underline{\sigma}}_{\alpha}^{2}$. But the components $\sigma_{\alpha}^{2}$ of $\sum_{\alpha=1}^{p} \sigma_{\alpha}^{2} Q_{\alpha}$ are unknown a-priori! One way out of this dilemma is to perform iterations. One starts with an initial guess for the $\sigma_{\alpha}^{2}$. Using these values, one computes with either (2.68) or (2.75) estimates for the $\sigma_{\alpha}^{2}$, which in the next cycle are considered the improved initial guess for $\sigma_{\alpha}^{2}$. And so on. The estimators obtained in each cycle are unbiased estimators of the $\sigma_{\alpha}^{2}$. However, they are not of minimum variance, not even after convergence of the iterations. Convergence is achieved if the initial guess for $\sigma_{\alpha}^{2}$ equals the computed estimate $\hat{\underline{\sigma}}_{\alpha}^{2}$. But since the computed estimate $\hat{\underline{\sigma}}_{\alpha}^{2}$ is not necessarily equal to $\sigma_{\alpha}^{2}$, the property of minimum variance may not necessarily be achieved. Hence, in practice one usually will have to be satisfied with almost minimum variance unbiased estimators. It will be clear that the amount in which the computed estimates lack the property of minimum variance, depends on the initial guess and the number of iterations performed. The above discussion presupposes that the variance components $\sigma_{\alpha}^{2}$ are needed in order to compute the estimators $\hat{\sigma}_{\alpha}^{2}$. Indeed, formulae (2.68) or (2.75) tell us that we need $Q_{y}=\sum_{\alpha=1}^{p} \sigma_{\alpha}^{2} Q_{\alpha}$ and thus $\sigma_{\alpha}^{2}$. There are however special cases where the $\sigma_{\alpha}^{2}$ are not needed a-priori! One such case we already met when discussing the estimator for the variance-factor of unit weight. Another important case where this holds true occurs when one wants to estimate the covariance matrix from repeated measurements.
consider the following model:

$$
\begin{equation*}
\underbrace{E\left\{\underline{y}_{i}\right\}}_{m \times 1}=\underbrace{A}_{m \times n} \underbrace{x_{i}}_{n \times 1}, \underbrace{E\left\{\left(\underline{y}_{i}-E\left\{\underline{y}_{i}\right\}\right)\left(\underline{y}_{j}-E\left\{\underline{y}_{j}\right\}\right)^{*}\right\}}_{m \times m}=\sigma_{i j} I_{m}, \quad i, j=1,2, \ldots, r \tag{2.80}
\end{equation*}
$$

Written out in full, this model reads

$$
\underbrace{E\{\{\underline{y}\}}_{m r \times 1}=E\left\{\left[\begin{array}{c}
\underline{y}_{1}  \tag{2.81}\\
\underline{y}_{2} \\
\vdots \\
\underline{y}_{r}
\end{array}\right]\right\}=\underbrace{\left[\begin{array}{cccc}
A & & & \\
& A & & \\
& & \ddots & \\
& & & A
\end{array}\right]}_{m r \times n r} \underbrace{\left[\begin{array}{c}
x_{1} \\
x_{2} \\
\vdots \\
x_{r}
\end{array}\right]}_{n r \times 1}, \quad Q_{y}=\underbrace{\left[\begin{array}{cccc}
\sigma_{1}^{2} I & \sigma_{12} I & \cdots & \sigma_{1 r} I \\
\sigma_{12} I & \sigma_{2}^{2} I & \cdots & \sigma_{2 r} I \\
\vdots & \vdots & \ddots & \vdots \\
\sigma_{1 r} I & \sigma_{2 r} I & \cdots & \sigma_{r}^{2} I
\end{array}\right]}_{m r \times m r}
$$

The unknowns in this model are the $n r \times 1$-number of elements of the vector $x$

$$
x=\underbrace{\left[\begin{array}{c}
x_{1}  \tag{2.82}\\
x_{2} \\
\vdots \\
x_{r}
\end{array}\right]}_{n r \times 1}
$$

and the $r(r+1) / 2$ number of elements $\sigma_{i}^{2}$ and $\sigma_{i j}$ of the symmetric matrix

$$
Q=\underbrace{\left[\begin{array}{cccc}
\sigma_{1}^{2} & \sigma_{12} & \cdots & \sigma_{1 r}  \tag{2.83}\\
\sigma_{12} & \sigma_{2}^{2} & \cdots & \sigma_{2 r} \\
\vdots & \vdots & \ddots & \vdots \\
\sigma_{1 r} & \sigma_{2 r} & \cdots & \sigma_{r}^{2}
\end{array}\right]}_{r \times r}
$$

Using the Kronecker product $\otimes$, we can write (2.81) with (2.82) and (2.83) as

$$
\begin{equation*}
\underbrace{E\{\underline{y}\}}_{m r \times 1}=\underbrace{(I \otimes A)}_{m r \times n r} \underbrace{x}_{n r \times 1}, \quad Q_{y}=\underbrace{Q \otimes I}_{m r \times m r} \tag{2.84}
\end{equation*}
$$

We shall now apply (2.75) to model (2.84) in order to find unbiased and minimum variance estimators for the elements of the matrix $Q$ of (2.83). With appropriate matrices $Q_{\alpha}$, matrix $Q$ can be written as

$$
\begin{equation*}
Q=\sum_{\alpha=1}^{r(r+1) / 2} \sigma_{\alpha}^{2} Q_{\alpha} \tag{2.85}
\end{equation*}
$$

where $\sigma_{\alpha}^{2}$ is respectively $\sigma_{1}^{2}, \sigma_{12}, \sigma_{13}, \ldots, \sigma_{r}^{2}$. Equation (2.74) reads then for the model (2.84)

$$
\begin{equation*}
\underline{l}_{\beta}=\frac{1}{2} \underline{y}^{*} P_{I \otimes A}^{\perp *} \cdot Q^{-1} \otimes I \cdot Q_{\beta} \otimes I \cdot Q^{-1} \otimes I \cdot P_{I \otimes A}^{\perp} \underline{y} \tag{2.86}
\end{equation*}
$$

with

$$
\begin{align*}
P_{I \otimes A}^{\perp} & =I \otimes I-P_{I \otimes A} \\
& =I \otimes I-I \otimes A\left[I \otimes A^{*} \cdot Q^{-1} \otimes I . I \otimes A\right]^{-1} I \otimes A^{*} \cdot Q^{-1} \otimes I  \tag{2.87}\\
& =I \otimes\left[I-A\left(A^{*} A\right)^{-1} A^{*}\right]=I \otimes P_{A}^{\perp}
\end{align*}
$$

and

$$
\begin{equation*}
\underline{y}=\sum_{i=1}^{r} e_{i} \otimes \underline{y}_{i}, \quad \text { with } \quad e_{i[r \times 1]}=(0 \cdots 010 \cdots 0)^{*} \tag{2.88}
\end{equation*}
$$

this gives

$$
\begin{equation*}
\underline{l}_{\beta}=\frac{1}{2} \sum_{i=1}^{r} e_{i}^{*} \otimes \underline{y}_{i}^{*} \cdot I \otimes P_{A}^{\perp *} \cdot Q^{-1} \otimes I \cdot Q_{\beta} \otimes I \cdot Q^{-1} \otimes I . I \otimes P_{A}^{\perp} \cdot \sum_{j=1}^{r} e_{j} \otimes \underline{y}_{j} \tag{2.89}
\end{equation*}
$$

or

$$
\begin{equation*}
\underline{l}_{\beta}=\frac{1}{2} \sum_{i=1}^{r} e_{i}^{*} \otimes \underline{y}_{i}^{*} \cdot Q^{-1} Q_{\beta} Q^{-1} \otimes P_{A}^{\perp} \cdot \sum_{j=1}^{r} e_{j} \otimes \underline{y}_{j} \tag{2.90}
\end{equation*}
$$

or

$$
\begin{equation*}
\underline{l}_{\beta}=\frac{1}{2} \sum_{i=1}^{r} \sum_{j=1}^{r} e_{i}^{*} Q^{-1} Q_{\beta} Q^{-1} e_{j} \underline{y}_{i}^{*} P_{A}^{\perp} \underline{y}_{j} \tag{2.91}
\end{equation*}
$$

Because of the symmetry of the matrices $Q^{-1} Q_{\beta} Q^{-1}$ this result can also be written as

$$
\begin{equation*}
\underline{l}_{\beta}=\frac{1}{2} \sum_{i=1}^{r}\left(e_{i}^{*} Q^{-1} Q_{\beta} Q^{-1} e_{i} \underline{y}_{i}^{*} P_{A}^{\perp} \underline{y}_{i}\right)+\frac{1}{2} .2 . \sum_{i=1}^{r} \sum_{j=i+1}^{r}\left(e_{i}^{*} Q^{-1} Q_{\beta} Q^{-1} e_{j} \underline{y}_{i}^{*} P_{A}^{\perp} \underline{y}_{j}\right) \tag{2.92}
\end{equation*}
$$

Let us now turn our attention to equation (2.72). This equation reads, for our model (2.84):

$$
\begin{equation*}
N_{\beta \alpha}=\frac{1}{2} \operatorname{trace}\left(Q_{\beta} \otimes I . Q^{-1} \otimes I . I \otimes P_{A}^{\perp} \cdot Q_{\alpha} \otimes I . Q^{-1} \otimes I . I \otimes P_{A}^{\perp}\right) \tag{2.93}
\end{equation*}
$$

or

$$
\begin{equation*}
N_{\beta \alpha}=\frac{1}{2} \operatorname{trace}\left(Q_{\beta} Q^{-1} Q_{\alpha} Q^{-1} \otimes P_{A}^{\perp}\right) \tag{2.94}
\end{equation*}
$$

or

$$
\begin{equation*}
N_{\beta \alpha}=\frac{1}{2} \operatorname{trace}\left(Q_{\beta} Q^{-1} Q_{\alpha} Q^{-1}\right) \operatorname{trace}\left(P_{A}^{\perp}\right) \tag{2.95}
\end{equation*}
$$

or

$$
\begin{equation*}
N_{\beta \alpha}=\frac{1}{2}(m-n) \operatorname{trace}\left(Q_{\beta} Q^{-1} Q_{\alpha} Q^{-1}\right) \tag{2.96}
\end{equation*}
$$

since $\operatorname{trace}\left(P_{A}^{\perp}\right)=\operatorname{rank}\left(P_{A}^{\perp}\right)=m-n$. Since the matrices $Q_{\alpha}, \alpha=1,2, \ldots, r(r+1) / 2$, of (2.85) are of the form

$$
Q_{\alpha}=\left\{\begin{array}{ccc}
e_{i} e_{j}^{*} & \text { for } \quad \sigma_{\alpha}^{2}:=\sigma_{i}^{2} & i=j  \tag{2.97}\\
e_{i} e_{j}^{*}+e_{j} e_{i}^{*} & \text { for } \quad \sigma_{\alpha}^{2}:=\sigma_{i j} & i \neq j
\end{array}\right.
$$

We may write, with the help of (2.96):

$$
\begin{align*}
\sum_{\alpha=1}^{r(r+1) / 2} N_{\beta \alpha} \hat{\sigma}_{\alpha}^{2} & =\frac{1}{2}(m-n) \sum_{i=1}^{r} \operatorname{trace}\left(Q_{\beta} Q^{-1} e_{i} e_{i}^{*} Q^{-1}\right) \hat{\sigma}_{i}^{2} \\
& +\frac{1}{2}(m-n) \sum_{i=1}^{r} \sum_{j=i+1}^{r} \operatorname{trace}\left(Q_{\beta} Q^{-1}\left(e_{i} e_{j}^{*}+e_{j} e_{i}^{*}\right) Q^{-1}\right) \hat{\sigma}_{i j} \tag{2.98}
\end{align*}
$$

This can also be written as:

$$
\begin{align*}
\sum_{\alpha=1}^{r(r+1) / 2} N_{\beta \alpha} \hat{\sigma}_{\alpha}^{2} & =\frac{1}{2}(m-n)\left\{\sum_{i=1}^{r}\left(e_{i}^{*} Q^{-1} Q_{\beta} Q^{-1} e_{i} \hat{\sigma}_{i}^{2}\right)\right. \\
& \left.+2 \sum_{i=1}^{r} \sum_{j=i+1}^{r}\left(e_{i}^{*} Q^{-1} Q_{\beta} Q^{-1} e_{j} \hat{\sigma}_{i j}\right)\right\} \tag{2.99}
\end{align*}
$$

Since $\sum_{\alpha=1}^{r(r+1) / 2} N_{\beta \alpha} \hat{\sigma}_{\alpha}^{2}=\underline{l}_{\beta}$, it follows from (2.92) and (2.99) that the unbiased and minimum variance estimators of the elements $\sigma_{i j}$ of the matrix $Q$ of (2.83) are given by:

$$
\begin{equation*}
\underline{\hat{\sigma}}_{i j}=\frac{\underline{y}_{i}^{*} P_{A}^{\perp} \underline{y}_{j}}{m-n}, \quad \text { and } \quad \hat{\sigma}_{i}^{2}=\frac{\underline{y}_{i}^{*} P_{A}^{\perp} \underline{y}_{i}}{m-n} \tag{2.100}
\end{equation*}
$$

Note that we need not know $Q$ in order to compute these estimates! If we denote $\underline{\hat{y}}_{i}=P_{A} \underline{y}_{i}$, then (2.100) can be written as

$$
\begin{equation*}
\underline{\hat{\underline{\sigma}}}_{i j}=\frac{1}{m-n} \sum_{k=1}^{m}\left(\underline{y}_{k i}-\underline{\hat{y}}_{k i}\right)\left(\underline{y}_{k j}-\underline{\hat{y}}_{k j}\right) \tag{2.101}
\end{equation*}
$$

From this follows that the covariance matrix $Q$ is estimated as

$$
\underbrace{\underline{Q}}_{r \times r}=\frac{1}{m-n} \sum_{k=1}^{m}\left(\begin{array}{c}
\underline{y}_{k 1}-\underline{\hat{y}}_{k 1}  \tag{2.102}\\
\underline{y}_{k 2}-\underline{\hat{y}}_{k 2} \\
\vdots \\
\underline{y}_{k r}-\underline{\hat{y}}_{k r}
\end{array}\right)\left(\begin{array}{c}
\underline{y}_{k 1}-\hat{y}_{k 1} \\
\underline{y}_{k 2}-\underline{\hat{y}}_{k 2} \\
\vdots \\
\underline{y}_{k r}-\underline{\hat{y}}_{k r}
\end{array}\right)^{*}
$$

If we define the matrices $\underline{Y}=\left[\underline{y}_{1} \underline{y}_{2} \cdots \underline{y}_{i} \cdots \underline{y}_{r}\right]$ and $\underline{\hat{Y}}=\left[\underline{\hat{y}}_{1} \underline{\hat{y}}_{2} \ldots \underline{\hat{y}}_{i} \ldots \underline{\hat{y}}_{r}\right]$ then (2.102) can alternatively be written as

$$
\begin{equation*}
\underbrace{\underline{Q}}_{r \times r}=\frac{1}{m-n} \underbrace{(\underline{Y}-\hat{Y})^{*}}_{r \times m} \underbrace{(\underline{Y}-\hat{\underline{Y}})}_{m \times r} \tag{2.103}
\end{equation*}
$$

In order to exemplify the theory, we consider two examples:

### 2.4.1 Example 1

We want to estimate the variance $\sigma^{2}$ of a distomat by measuring an unknown distance $x$ an $m$ number of times. We assume that the observations are normally distributed. Model (2.81) reads
then for our case:

$$
E\{\underline{y}\}=E\left\{\left[\begin{array}{c}
\underline{y}_{1}  \tag{2.104}\\
\underline{y}_{2} \\
\vdots \\
\underline{y}_{m}
\end{array}\right]\right\}=\left[\begin{array}{c}
1 \\
1 \\
\vdots \\
1
\end{array}\right] x, \quad Q_{y}=\sigma^{2} I_{m}
$$

Thus $r=1, n=1$ and $A=\left[\begin{array}{llll}1 & 1 & \ldots\end{array}\right]^{*}$. Hence, $P_{A} \underline{y}$ is

$$
\underline{\hat{y}}=P_{A} \underline{y}=\left[\begin{array}{c}
1  \tag{2.105}\\
1 \\
\vdots \\
1
\end{array}\right] \frac{1}{m} \sum_{i=1}^{m} \underline{y}_{i}=\left[\begin{array}{c}
1 \\
1 \\
\vdots \\
1
\end{array}\right] \underline{\bar{y}}
$$

With (2.102) the result reads then

$$
\begin{equation*}
\underline{\hat{\sigma}}^{2}=\frac{1}{m-1} \sum_{k=1}^{m}\left(\underline{y}_{k}-\underline{\bar{y}}\right)^{2}, E\left\{\underline{\hat{\sigma}}^{2}\right\}=\sigma^{2}, \sigma_{\hat{\sigma}^{2}}^{2}=\frac{2 \sigma^{4}}{m-1} \tag{2.106}
\end{equation*}
$$

Note that this result can also be obtained from (2.79), the estimator of the variance factor of unit weight.

### 2.4.2 Example 2

We want to estimate the $2 \times 2$ variance-covariance matrix of a digitizer by measuring the coordinates of an unknown point an $m$-number of times. We assume that the observations are normally distributed. Model (2.81) reads then for our case

$$
E\{\underline{y}\}=E\left\{\left[\begin{array}{l}
\underline{y}_{1}  \tag{2.107}\\
\underline{y}_{2}
\end{array}\right]\right\}=E\left\{\left[\begin{array}{c}
\underline{y}_{11} \\
\vdots \\
\underline{y}_{m 1} \\
\underline{y}_{12} \\
\vdots \\
\underline{y}_{m 2}
\end{array}\right]\right\}=\left[\begin{array}{cc}
1 & 0 \\
\vdots & \vdots \\
1 & 0 \\
0 & 1 \\
\vdots & \vdots \\
0 & 1
\end{array}\right]\left[\begin{array}{c}
x_{1} \\
x_{2}
\end{array}\right], \quad Q_{y}=\left[\begin{array}{cc}
\sigma_{1}^{2} I_{m} & \sigma_{12} I_{m} \\
\sigma_{12} I_{m} & \sigma_{2}^{2} I_{m}
\end{array}\right]
$$

Thus $r=2, n=1$ and $A=\left[\begin{array}{lll}1 & \cdots & 1\end{array}\right]^{*}$. Hence, $P_{A} \underline{y}_{i}$ is

$$
P_{A} \underline{y}_{i}=\left[\begin{array}{c}
1  \tag{2.108}\\
\vdots \\
1
\end{array}\right] \frac{1}{m} \sum_{l=1}^{m} \underline{y}_{l i}=\underline{\bar{y}}_{i}, \quad i=1,2
$$

With (2.102) the results read then

$$
\left[\begin{array}{cc}
\hat{\sigma}_{1}^{2} & \hat{\sigma}_{12}  \tag{2.109}\\
\hat{\sigma}_{12} & \hat{\hat{\sigma}}_{2}^{2}
\end{array}\right]=\frac{1}{m-1} \sum_{k=1}^{m}\left[\begin{array}{l}
\underline{y}_{k 1}-\bar{y}_{1} \\
\underline{y}_{k 2}-\underline{\bar{y}}_{2}
\end{array}\right]\left[\begin{array}{l}
\underline{y}_{k 1}-\overline{\bar{y}}_{1} \\
\underline{y}_{k 2}-\underline{\bar{y}}_{2}
\end{array}\right]^{*}
$$

The corresponding covariance matrix is given by

$$
D\left\{\left[\begin{array}{c}
\hat{\sigma}_{1}^{2}  \tag{2.110}\\
\hat{\sigma}_{12} \\
\hat{\underline{\sigma}}_{2}^{2}
\end{array}\right]\right\}=\frac{2}{m-1}\left(\sigma_{1}^{2} \sigma_{2}^{2}-\sigma_{12}^{2}\right)^{2}\left[\begin{array}{ccc}
\sigma_{2}^{4} & -2 \sigma_{2}^{2} \sigma_{12} & \sigma_{12}^{2} \\
& 2\left(\sigma_{1}^{2} \sigma_{2}^{2}+\sigma_{12}^{2}\right) & -2 \sigma_{1}^{2} \sigma_{12} \\
& & \sigma_{1}^{4}
\end{array}\right]^{-1}
$$

In case $\sigma_{1}=\sigma_{2}=\sigma$ and $\sigma_{12}=0$, it follows:

$$
D\left\{\left[\begin{array}{c}
\hat{\sigma}_{1}^{2}  \tag{2.111}\\
\hat{\sigma}_{12} \\
\hat{\underline{\sigma}}_{2}^{2}
\end{array}\right]\right\}=\frac{2 \sigma^{4}}{m-1}\left[\begin{array}{ccc}
1 & 0 & 0 \\
0 & 0.5 & 0 \\
0 & 0 & 1
\end{array}\right]
$$

## Chapter 3

## On the Distribution of Variance Components

### 3.1 Quadratic Forms in Normal Variables

If we denote the inverse of the normal matrix in (2.68) as $N_{\beta \alpha}^{-1}$, it follows that the least-squares estimator of $\sigma_{\beta}^{2}$ is given as

$$
\begin{equation*}
\hat{\underline{\sigma}}_{\beta}^{2}=\frac{1}{2} \sum_{\alpha=1}^{p} N_{\beta \alpha}^{-1} \underline{t}^{*} Q_{t}^{-1} B^{*} Q_{\alpha} B Q_{t}^{-1} \underline{t} \tag{3.1}
\end{equation*}
$$

or as

$$
\begin{equation*}
\hat{\underline{\sigma}}_{\beta}^{2}=\underline{t}^{*}\left(Q_{t}^{-1} B^{*} \frac{1}{2} \sum_{\alpha=1}^{p} N_{\beta \alpha}^{-1} Q_{\alpha} B Q_{t}^{-1}\right) \underline{t} \tag{3.2}
\end{equation*}
$$

Hence, each least-squares estimator of a variance-component can be written as a quadratic form in the normal vector $t$ :

$$
\begin{equation*}
\hat{\hat{\sigma}}_{\beta}^{2}=\underline{t}^{*} A_{\beta} \underline{t} \tag{3.3}
\end{equation*}
$$

with

$$
\begin{equation*}
A_{\beta}=Q_{t}^{-1} B^{*} \frac{1}{2} \sum_{\alpha=1}^{p} N_{\beta \alpha}^{-1} Q_{\alpha} B Q_{t}^{-1} \tag{3.4}
\end{equation*}
$$

In the following, we shall assume that the symmetric matrix $A_{\beta}$ is non-negative definite. In practice, this may not be the case, since, as we know, negative estimates of the variance-component are possible. In order to derive the distribution of $\hat{\sigma}_{\beta}^{2}$ for non-negative matrices $A_{\beta}$, we need the distribution of $\underline{t}^{*} A_{\beta} \underline{\underline{t}}$. The following theorem gives a general representation of the distribution of $\underline{t}^{*} A \underline{t}$.

Theorem: Let the $b \times 1$ vector $\underline{t}$ be normally distributed with mean $E\{\underline{t}\}=t$ and positive definite covariance matrix $Q_{t}$. Let $A$ be a symmetric non-negative definite matrix of order $b$. Then there exists a positive-definite diagonal matrix $\Lambda_{r}=\operatorname{diag}\left(\lambda_{1}, \lambda_{2}, \cdots, \lambda_{r}\right)$ and a vector $u \in \mathbb{R}^{r}$ such that

$$
\begin{equation*}
\underline{t}^{*} A \underline{t}=(\underline{z}+u)^{*} \Lambda_{r}(\underline{z}+u)=\sum_{i=1}^{r} \lambda_{i}\left(\underline{z}_{i}+u_{i}\right)^{2} \tag{3.5}
\end{equation*}
$$

where $\underline{z}$ has the standard normal distribution, i.e. $\underline{z} \sim N\left(0, I_{r}\right)$. The number $r$ is the rank of $A Q_{t}$ or $Q_{t} A$. The diagonal elements of $\Lambda_{r}$ are the $r$ positive eigenvalues of $A Q_{t}$ or $Q_{t} A$. And if $U_{r} \Lambda_{r} U_{r}^{*}$ is the singular value decomposition of $Q_{t}^{1 / 2} A Q_{t}^{1 / 2}$, i.e., $Q_{t}^{1 / 2} A Q_{t}^{1 / 2}=U_{r} \Lambda_{r} U_{r}^{*}$, with $Q_{t}^{1 / 2}$ a square-root of $Q_{t}$, i.e., $Q_{t}=Q_{t}^{1 / 2} Q_{t}^{1 / 2}$, then the $r \times 1$ vector $u$ can be computed as

$$
\begin{equation*}
u=U_{r}^{*} Q_{t}^{-1 / 2} t \tag{3.6}
\end{equation*}
$$

Proof: If we define the random vector $\underline{x}=Q_{t}^{-1 / 2}(\underline{t}-t)$, then clearly $\underline{x}$ has a standard normal distribution, i.e., $\underline{x} \sim N\left(0, I_{b}\right)$. Substitution of $\underline{t}=t+Q_{t}^{1 / 2} \underline{x}$ in $\underline{t}^{*} A \underline{t}$ gives

$$
\begin{equation*}
\underline{t}^{*} A \underline{t}=t^{*} A t+2 t^{*} A Q_{t}^{1 / 2} \underline{x}+\underline{x}^{*} Q_{t}^{1 / 2} A Q_{t}^{1 / 2} \underline{x} \tag{3.7}
\end{equation*}
$$

Since the matrix $Q_{t}^{1 / 2} A Q_{t}^{1 / 2}$ is symmetric and non-negative definite it has real-valued non-negative eigenvalues and corresponding orthonormal eigenvectors. If we collect the $b$-number of eigenvalues in the $b \times b$ diagonal matrix $\Lambda$ and the corresponding orthonormal eigenvectors as columns in the $b \times b$ matrix $U$ then

$$
\begin{equation*}
Q_{t}^{1 / 2} A Q_{t}^{1 / 2}=U \Lambda U^{*} \tag{3.8}
\end{equation*}
$$

with

$$
\begin{equation*}
U^{*} U=U U^{*}=I_{b} \tag{3.9}
\end{equation*}
$$

If $\operatorname{rank}\left(Q_{t}^{1 / 2} A Q_{t}^{1 / 2}\right)=r$, then $r$-number of eigenvalues are positive and $(b-r)$-number of eigenvalues are zero. We may therefore partition (3.8) as

$$
\begin{align*}
Q_{t}^{1 / 2} A Q_{t}^{1 / 2} & =\left[U_{r} U_{b-r}\right]\left[\begin{array}{cc}
\Lambda_{r} & 0 \\
0 & 0
\end{array}\right]\left[\begin{array}{c}
U_{r}^{*} \\
U_{b-r}^{*}
\end{array}\right] \\
& =U_{r} \Lambda_{r} U_{r}^{*} \tag{3.10}
\end{align*}
$$

with

$$
\begin{equation*}
U_{r}^{*} U_{r}=I_{r} \tag{3.11}
\end{equation*}
$$

Substitution of (3.10) into (3.7) gives

$$
\begin{equation*}
\underline{t}^{*} A \underline{t}=t^{*} A t+2 t^{*} Q_{t}^{-1 / 2} U_{r} \Lambda_{r} U_{r}^{*} \underline{x}+\underline{x}^{*} U_{r} \Lambda_{r} U_{r}^{*} \underline{x} \tag{3.12}
\end{equation*}
$$

or

$$
\begin{align*}
\underline{t}^{*} A \underline{t} & =t^{*} A t-t^{*} Q_{t}^{-1 / 2} U_{r} \Lambda_{r} U_{r}^{*} Q_{t}^{-1 / 2} t \\
& +\left(U_{r}^{*} \underline{x}+U_{r}^{*} Q_{t}^{-1 / 2} t\right)^{*} \Lambda_{r}\left(U_{r}^{*} \underline{x}+U_{r}^{*} Q_{t}^{-1 / 2} t\right) \tag{3.13}
\end{align*}
$$

or

$$
\begin{align*}
\underline{t}^{*} A \underline{t} & =t^{*} A t-t^{*} Q_{t}^{-1 / 2} Q_{t}^{1 / 2} A Q_{t}^{1 / 2} Q_{t}^{-1 / 2} t \\
& +\left(U_{r}^{*} \underline{x}+U_{r}^{*} Q_{t}^{-1 / 2} t\right)^{*} \Lambda_{r}\left(U_{r}^{*} \underline{x}+U_{r}^{*} Q_{t}^{-1 / 2} t\right) \tag{3.14}
\end{align*}
$$

or

$$
\begin{equation*}
\underline{t}^{*} A \underline{t}=(\underline{z}+u)^{*} \Lambda_{r}(\underline{z}+u) \tag{3.15}
\end{equation*}
$$

with

$$
\begin{align*}
\underline{z} & =U_{r}^{*} \underline{x}=U_{r}^{*} Q_{t}^{-1 / 2}(\underline{t}-t) \\
u & =U_{r}^{*} Q_{t}^{-1 / 2} t \tag{3.16}
\end{align*}
$$

Since $\underline{x}$ is distributed as $\underline{x} \sim N\left(0, I_{b}\right)$, and $U_{r}^{*} U_{r}=I_{r}$, it follows that $\underline{z}=U_{r}^{*} \underline{x}$ is distributed as $\underline{z} \sim N\left(0, I_{r}\right)$. Note that since $\left|Q_{t}^{1 / 2} A Q_{t}^{1 / 2}-\lambda I_{b}\right|=\left|A Q_{t}-\lambda I_{b}\right|=\left|Q_{t} A-\lambda I_{b}\right|$, the eigenvalues of $Q_{t}^{1 / 2} A Q_{t}^{1 / 2}, A Q_{t}$ and $Q_{t} A$ are the same. End of proof.

The above theorem says that $\underline{t}^{*} A \underline{t}$ is distributed as a linear combination of $r$ independent noncentral $\chi^{2}$-distribution with 1 degree of freedom and non-centrality parameters $u_{i}^{2}, i=1,2, \cdots, r$, i.e.,

$$
\begin{equation*}
\underline{t}^{*} A \underline{t} \sim \sum_{i=1}^{r} \lambda_{i} \chi^{2}\left(1, u_{i}^{2}\right) \tag{3.17}
\end{equation*}
$$

From this follows that if all the positive eigenvalues of $A Q_{t}$ equal 1 , then $\underline{t}^{*} A \underline{t}$ is distributed as a non-central $\chi^{2}$-distribution with $r$ degrees of freedom and non-centrality parameter $u^{*} u=$ $t^{*} Q_{t}^{-1 / 2} U_{r} I_{r} U_{r}^{*} Q_{t}^{-1 / 2} t=t^{*} A t:$

$$
\begin{equation*}
\underline{t}^{*} A \underline{t} \sim \chi^{2}\left(r, t^{*} A t\right) \text { if } \Lambda_{r}=I_{r} . \tag{3.18}
\end{equation*}
$$

Since the mean of a central $\chi^{2}$-distribution with 1 degree of freedom is 1 , the mean of $\underline{t}^{*} A \underline{t}$ follows from (3.5) as

$$
\begin{equation*}
E\left\{\underline{t}^{*} A \underline{t}\right\}=\sum_{i=1}^{r} \lambda_{i}+\sum_{i=1}^{r} \lambda_{i} u_{i}^{2}=\operatorname{trace}\left(A Q_{t}\right)+t^{*} A t \tag{3.19}
\end{equation*}
$$

Since the variance of the non-central $\chi^{2}$-distribution with 1 degree of freedom and non-centrality parameter $u_{i}^{2}$ is $2\left(1+2 u_{i}^{2}\right)$, the variance of $\underline{t}^{*} A \underline{t}$ follows from (3.5) as

$$
\begin{equation*}
\sigma_{\underline{t}^{*} A \underline{t}}^{2}=2 \sum_{i=1}^{r} \lambda_{i}^{2}+4 \sum_{i=1}^{r} \lambda_{i}^{2} u_{i}^{2}=2 \operatorname{trace}\left(A Q_{t} A Q_{t}\right)+4 t^{*} A Q_{t} A t \tag{3.20}
\end{equation*}
$$

### 3.2 The Distribution of $\hat{\underline{\sigma}}_{\beta}^{2}$

We shall assume that the estimate $\hat{\sigma}_{\beta}^{2}$ of $\sigma_{\beta}^{2}$ are non-negative. With the theorem of the previous section and (3.3) and (3.4) we then have the following result:

Corollary: The variance-component estimator $\hat{\sigma}_{\beta}^{2}$ is distributed as

$$
\begin{equation*}
\hat{\underline{\sigma}}_{\beta}^{2} \sim \sum_{i=1}^{r} \lambda_{i} \chi_{i}^{2}(1,0) \tag{3.21}
\end{equation*}
$$

where the $\chi_{i}^{2}$ are mutually independent and the $\lambda_{i}$ are the $r$ positive eigenvalues of

$$
\begin{equation*}
\left|B^{*}\left[\sum_{\alpha=1}^{p}\left(\frac{1}{2} N_{\beta \alpha}^{-1}-\lambda \sigma_{\alpha}^{2}\right) Q_{\alpha}\right] B\right|=0 \tag{3.22}
\end{equation*}
$$

Note that since the matrix $B^{*}$ is of the order $b \times m$, the number of positive eigenvalues, $r$, never exceed $b$.
The result (3.22) is expressed in terms of the matrix $B$ which however is often not explicitly available. We shall therefore reexpress (3.22) in terms of $Q_{y}=\sum_{\alpha=1}^{p} \sigma_{\alpha}^{2} Q_{\alpha}$ and $Q_{\hat{e}}$. In order to do this, we need the following two properties of the determinant of a matrix:

1. Let $X$ and $Y$ be two arbitrary matrices of order $n \times n$. Then

$$
\begin{equation*}
|X Y|=|X| .|Y| \tag{3.23}
\end{equation*}
$$

2. Let $X$ and $Y^{*}$ be any two matrices of order $m \times n$ and suppose $m \geq n$. Then

$$
\begin{equation*}
\left|X Y-\lambda I_{m}\right|=(-\lambda)^{m-n}\left|Y X-\lambda I_{n}\right| \tag{3.24}
\end{equation*}
$$

The determinant of (3.22) can be written as

$$
\begin{aligned}
\left|B^{*}\left[\sum_{\alpha=1}^{p}\left(\frac{1}{2} N_{\beta \alpha}^{-1}-\lambda \sigma_{\alpha}^{2}\right) Q_{\alpha}\right] B\right| & =\left|B^{*}\left[\sum_{\alpha=1}^{p} \frac{1}{2} N_{\beta \alpha}^{-1} Q_{\alpha}\right] B-\lambda B^{*} \sum_{\alpha=1}^{p} \sigma_{\alpha}^{2} Q_{\alpha} B\right| \\
& =\left|B^{*}\left[\sum_{\alpha=1}^{p} \frac{1}{2} N_{\beta \alpha}^{-1} Q_{\alpha}\right] B-\lambda B^{*} Q_{y} B\right|
\end{aligned}
$$

with (3.23) and (3.24) one gets

$$
\begin{aligned}
\left|B^{*}\left[\sum_{\alpha=1}^{p}\left(\frac{1}{2} N_{\beta \alpha}^{-1}-\lambda \sigma_{\alpha}^{2}\right) Q_{\alpha}\right] B\right| & =\left|B^{*}\left[\sum_{\alpha=1}^{p} \frac{1}{2} N_{\beta \alpha}^{-1} Q_{\alpha}\right] B\left(B^{*} Q_{y} B\right)^{-1}-\lambda I_{b}\right| \cdot\left|B^{*} Q_{y} B\right| \\
& =(-\lambda)^{b-m}\left|\sum_{\alpha=1}^{p} \frac{1}{2} N_{\beta \alpha}^{-1} Q_{\alpha} B\left(B^{*} Q_{y} B\right)^{-1} B^{*}-\lambda I_{m}\right| \cdot\left|B^{*} Q_{y} B\right|
\end{aligned}
$$

if $\lambda \neq 0$. From this follows that for non-zero eigenvalues, (3.22) is equivalent to

$$
\begin{equation*}
\left|\sum_{\alpha=1}^{p} \frac{1}{2} N_{\beta \alpha}^{-1} Q_{\alpha} B\left(B^{*} Q_{y} B\right)^{-1} B^{*}-\lambda I_{m}\right|=0 \tag{3.25}
\end{equation*}
$$

With $Q_{\hat{e}}=Q_{y} B\left(B^{*} Q_{y} B\right)^{-1} B^{*} Q_{y}$ this gives

$$
\begin{equation*}
\left|\sum_{\alpha=1}^{p} \frac{1}{2} N_{\beta \alpha}^{-1} Q_{\alpha} Q_{y}^{-1} Q_{\hat{e}} Q_{y}^{-1}-\lambda I_{m}\right|=0 \tag{3.26}
\end{equation*}
$$

or with (3.24)

$$
\begin{equation*}
\left|Q_{y}^{-1}\left(\sum_{\alpha=1}^{p} \frac{1}{2} N_{\beta \alpha}^{-1} Q_{\alpha}\right) Q_{y}^{-1} Q_{\hat{e}}-\lambda I_{m}\right|=0 \tag{3.27}
\end{equation*}
$$

The result (3.22) can therefore be rephrased as:
Final Result: The variance-component estimator $\hat{\underline{\sigma}}_{\beta}^{2}$ is distributed as

$$
\begin{equation*}
\hat{\underline{\sigma}}_{\beta}^{2} \sim \sum_{i=1}^{r} \lambda_{i} \chi_{i}^{2}(1,0) \tag{3.28}
\end{equation*}
$$

where the $\chi_{i}^{2}$ are mutually independent and the $\lambda_{i}$ are the $r$ positive eigenvalues of

$$
\begin{equation*}
\left|Q_{y}^{-1}\left(\sum_{\alpha=1}^{p} \frac{1}{2} N_{\beta \alpha}^{-1} Q_{\alpha}\right) Q_{y}^{-1} Q_{\hat{e}}-\lambda I_{m}\right|=0 \tag{3.29}
\end{equation*}
$$

To see this result at work let us derive the distribution of the variance-factor of unit weight. In this case, we have $p=1, Q_{y}=\sigma_{1}^{2} Q_{1}$ and $N_{11}=\frac{1}{2}(m-n) \sigma_{1}^{-4}$. The above eigenvalue problem becomes then

$$
\begin{equation*}
\left|Q_{y}^{-1} \frac{1}{2}\left[\frac{1}{2}(m-n) \sigma_{1}^{-4}\right]^{-1} Q_{1} \sigma_{1}^{-2} Q_{1}^{-1} Q_{\hat{e}}-\lambda I_{m}\right|=0 \tag{3.30}
\end{equation*}
$$

or

$$
\begin{equation*}
\left|\left[\sigma_{1}^{-2}(m-n)\right]^{-1} Q_{\hat{e}} Q_{y}^{-1}-\lambda I_{m}\right|=0 \tag{3.31}
\end{equation*}
$$

or with $Q_{\hat{e}} Q_{y}^{-1}=P_{A}^{\perp}$

$$
\begin{equation*}
\left|P_{A}^{\perp}-\lambda \sigma_{1}^{-2}(m-n) I_{m}\right|=0 \tag{3.32}
\end{equation*}
$$

Since the eigenvalues of a projector are 1 or 0 , it follows since $\operatorname{rank}\left(P_{A}^{\perp}\right)=m-n$ that the positive eigenvalues are

$$
\begin{equation*}
\lambda_{1}=\lambda_{2}=\cdots=\lambda_{m-n}=\left[\sigma_{1}^{-2}(m-n)\right]^{-1} \tag{3.33}
\end{equation*}
$$

From (3.29) follows then that the variance-factor of unit weight $\hat{\sigma}_{1}^{2}$ is distributed as

$$
\begin{equation*}
\hat{\underline{\sigma}}_{1}^{2} \sim \frac{\sigma_{1}^{2} \chi^{2}(m-n, 0)}{m-n} \tag{3.34}
\end{equation*}
$$

This is a well-known result and very simple indeed. For general case of more than one variancecomponent, the eigenvalues $\lambda_{i}$ of (3.29) will usually differ mutually and consequently the distribution of $\hat{\sigma}_{\beta}^{2}$ will be a very complicated one. As far as I know no practical closed form expression for the cumulative distribution function of $\hat{\underline{\sigma}}_{\beta}^{2}$ is available. This function is needed to perform hypothesis testing, to compute critical values and to compute the power (reliability). Fortunately, however, asymptotic expansions which can be used for computer calculation are available ${ }^{1}$. Also suitable (and may be practical useful) approximations are available. Once the distribution of $\hat{\sigma}_{\beta}^{2}$ is available one can think of testing hypotheses. One possible approach would be the following: Assume the null hypothesis as

$$
H_{0}: E\{\underline{t}\}=0, \quad Q_{t}=B^{*} \sum_{\alpha=1}^{p} \sigma_{\alpha}^{2} Q_{\alpha} B, \begin{cases}\sigma_{\alpha}^{2} \neq 1 & \text { for } \quad \alpha=1,2, \cdots, p, \alpha \neq i  \tag{3.35}\\ \sigma_{\alpha}^{2}=1 & \text { for } \quad \alpha=i\end{cases}
$$

Assume the alternative hypothesis as

$$
\begin{equation*}
H_{A}: E\{\underline{t}\}=0, \quad Q_{t}=B^{*} \sum_{\alpha=1}^{p} \sigma_{\alpha}^{2} Q_{\alpha} B, \quad \sigma_{\alpha}^{2} \neq 1 \text { for } \alpha=1,2, \cdots, p \tag{3.36}
\end{equation*}
$$

Compute the estimator of $\sigma_{i}^{2}$ under $H_{A}$. This estimator depends however on the unknown $\sigma_{\alpha}^{2}$, $\alpha=$ $1,2, \cdots, p$. Approximate the estimator $\hat{\sigma}_{i}^{2}$ of $\sigma_{i}^{2}$ under $H_{A}$ therefore by assuming that $\sigma_{\alpha}^{2}=1, \alpha=$ $1,2, \cdots, p$, and call this approximate estimator $\hat{\underline{\sigma}}_{i}^{\prime 2}$. As we know, this approximate estimator is still unbiased. Then derive the distribution of $\underline{\hat{\sigma}}_{i}^{\prime 2}$. This distribution depends however under $H_{0}$ still on the unknown $\sigma_{\alpha}^{2}, \alpha=1,2, \cdots, p, \alpha \neq i$. One can approximate this distribution by replacing the unknown $\sigma_{\alpha}^{2}$ by the estimates $\hat{\sigma}_{\alpha}^{\prime 2}, \alpha=1,2, \cdots, p, \alpha \neq i$. After this one can perform the significance test: $\sigma_{i}^{2}=1$ or $\sigma_{i}^{2} \neq 1$.
Another approach would be the following: Assume the null hypothesis as

$$
\begin{equation*}
H_{0}: E\{\underline{t}\}=0, Q_{t}=B^{*} \sum_{\alpha=1}^{p} Q_{\alpha} B \tag{3.37}
\end{equation*}
$$

and the the alternative hypothesis as

$$
\begin{equation*}
H_{A_{i}}: E\{\underline{t}\}=0, Q_{t}=B^{*}\left(\sum_{\alpha=1 \alpha \neq i}^{p} Q_{\alpha}+\sigma_{i}^{2} Q_{i}\right) B, \sigma_{i}^{2} \neq 1 \tag{3.38}
\end{equation*}
$$

This approach parallels the data snooping approach and it has some distinct advantages over the above first approach. First of all, the null hypothesis is completely specified, it is a so-called simple hypothesis. Secondly, there is only one unknown, namely $\sigma_{i}^{2}$, in the alternative hypothesis. This is advantageous from a computational point of view. In the following section we will consider the case of least-squares estimation under the above $H_{A_{i}}$.

### 3.3 LSQ Estimation in Case $Q_{t}=B^{*}\left(\sum_{\alpha=1 \alpha \neq i}^{p} Q_{\alpha}+\sigma_{i}^{2} Q_{i}\right) B$

If the covariance matrix of $\underline{t}$ is assumed to take the form

$$
\begin{equation*}
E\left\{\underline{t t^{*}}\right\}=\sum_{\alpha=1}^{p} B^{*} Q_{\alpha} B+\sigma_{i}^{2} B^{*} Q_{i} B \tag{3.39}
\end{equation*}
$$

the observation equations of the linear model take the form

$$
\begin{equation*}
E\left\{\operatorname{vec}\left(\underline{t t^{*}}\right)\right\}-\operatorname{vec}\left(\sum_{\alpha=1 \alpha \neq i}^{p} B^{*} Q_{\alpha} B\right)=\operatorname{vec}\left(B^{*} Q_{i} B\right) \sigma_{i}^{2} \tag{3.40}
\end{equation*}
$$

Thus instead of (2.8), we now have (3.40). Note that since a constant vector is subtracted from $\operatorname{vec}\left(\underline{t t}^{*}\right)$, the covariance matrix of $\operatorname{vec}\left(\underline{t t}^{*}\right)$ can still be used. With (2.63) we get for the above model

$$
\begin{equation*}
N=\frac{1}{2} \operatorname{trace}\left(B^{*} Q_{i} B Q_{t}^{-1} B^{*} Q_{i} B Q_{t}^{-1}\right) \tag{3.41}
\end{equation*}
$$

[^1]And with (2.68) we get for the above model

$$
\begin{equation*}
\underline{l}=\frac{1}{2} \operatorname{trace}\left(B^{*} Q_{i} B Q_{t}^{-1}\left[\underline{t t}^{*}-\sum_{\alpha=1 \alpha \neq i}^{p} B^{*} Q_{\alpha} B\right] Q_{t}^{-1}\right) \tag{3.42}
\end{equation*}
$$

or

$$
\begin{equation*}
\underline{l}=\frac{1}{2} \underline{t} Q_{t}^{-1} B^{*} Q_{i} B Q_{t}^{-1} \underline{t}-\frac{1}{2} \operatorname{trace}\left(B^{*} Q_{i} B Q_{t}^{-1} \sum_{\alpha=1 \alpha \neq i}^{p} B^{*} Q_{\alpha} B Q_{t}^{-1}\right) \tag{3.43}
\end{equation*}
$$

or with $Q_{t}=\sum_{\alpha=1 \alpha \neq i}^{p} B^{*} Q_{\alpha} B+\sigma_{i}^{2} B^{*} Q_{i} B$ :

$$
\begin{equation*}
\underline{l}=\frac{1}{2} \underline{t} Q_{t}^{-1} B^{*} Q_{i} B Q_{t}^{-1} \underline{t}-\frac{1}{2} \operatorname{trace}\left(B^{*} Q_{i} B Q_{t}^{-1}\right)+\frac{1}{2} \sigma_{i}^{2} \operatorname{trace}\left(B^{*} Q_{i} B Q_{t}^{-1} B^{*} Q_{i} B Q_{t}^{-1}\right) \tag{3.44}
\end{equation*}
$$

With (3.41) the estimator $\hat{\sigma}_{i}^{2}=N^{-1} \underline{l}$ reads therefore:
Final Result:

$$
\begin{equation*}
\hat{\hat{\sigma}}_{i}^{2}=\sigma_{i}^{2}+\frac{\underline{t} Q_{t}^{-1} B^{*} Q_{i} B Q_{t}^{-1} \underline{t}-\operatorname{trace}\left(B^{*} Q_{i} B Q_{t}^{-1}\right)}{\operatorname{trace}\left(B^{*} Q_{i} B Q_{t}^{-1} B^{*} Q_{i} B Q_{t}^{-1}\right)} \tag{3.45}
\end{equation*}
$$

with $E\left\{\hat{\hat{\sigma}}_{i}^{2}\right\}=\sigma_{i}^{2}$ and

$$
\begin{equation*}
\sigma_{\hat{\sigma}_{i}^{2}}^{2}=2\left[\operatorname{trace}\left(B^{*} Q_{i} B Q_{t}^{-1} B^{*} Q_{i} B Q_{t}^{-1}\right)\right]^{-1} \tag{3.46}
\end{equation*}
$$

With (3.5) of the theorem of section one, the distribution of $\hat{\sigma}_{i}^{2}$ follows as:

$$
\begin{equation*}
\hat{\hat{\sigma}}_{i}^{2} \sim \sigma_{i}^{2}+\frac{\sum_{j=1}^{r} \lambda_{j} \chi_{j}^{2}(1,0)-\sum_{j=1}^{r} \lambda_{j}}{\sum_{j=1}^{r} \lambda_{j}^{2}} \tag{3.47}
\end{equation*}
$$

where $\lambda_{j}, j=1,2, \cdots, r$ are the $r$ positive eigenvalues of

$$
\begin{equation*}
\left|B^{*} Q_{i} B-\lambda Q_{t}\right|=0 \tag{3.48}
\end{equation*}
$$

or of

$$
\begin{equation*}
\left|Q_{y}^{-1} Q_{i} Q_{y}^{-1} Q_{\hat{e}}-\lambda I_{m}\right|=0 \tag{3.49}
\end{equation*}
$$

The problem of hypothesis testing may now be tackled as follows: Assume the null hypothesis as

$$
\begin{equation*}
H_{0}: E\{\underline{t}\}=0, Q_{t}=\sum_{\alpha=1}^{p} B^{*} Q_{\alpha} B \tag{3.50}
\end{equation*}
$$

and the the alternative hypothesis as

$$
\begin{equation*}
H_{A_{i}}: E\{\underline{t}\}=0, Q_{t}=\sum_{\alpha=1 \alpha \neq i}^{p} B^{*} Q_{\alpha} B+\sigma_{i}^{2} B^{*} Q_{i} B \tag{3.51}
\end{equation*}
$$

Note that although the estimator $\hat{\sigma}_{i}^{2}$ of (3.45) can not be computed in practice because of the unknown $\sigma_{i}^{2}$, its distribution is known under $H_{0}$ ! Instead of computing $\hat{\sigma}_{i}^{2}$ we therefore approximate this estimator by an estimator $\hat{\sigma}_{i}^{\prime 2}$, which is obtained by setting $\sigma_{i}^{2}=1$ in (3.45). The approximate estimator reads therefore

$$
\begin{equation*}
\underline{\hat{\sigma}}_{i}^{\prime 2}=1+\frac{\underline{t} \bar{Q}_{t}^{-1} B^{*} Q_{i} B \bar{Q}_{t}^{-1} \underline{t}-\operatorname{trace}\left(B^{*} Q_{i} B \bar{Q}_{t}^{-1}\right)}{\operatorname{trace}\left(B^{*} Q_{i} B \bar{Q}_{t}^{-1} B^{*} Q_{i} B \bar{Q}_{t}^{-1}\right)} \tag{3.52}
\end{equation*}
$$

with

$$
\begin{equation*}
\bar{Q}_{t}=\sum_{\alpha=1}^{p} B^{*} Q_{\alpha} B \tag{3.53}
\end{equation*}
$$

We know from our theory that this approximate estimator is still an unbiased estimator of $\sigma_{i}^{2}$ (however not of minimum variance anymore). Let us verify this for (3.52). With $A=\bar{Q}_{t}^{-1} B^{*} Q_{i} B \bar{Q}_{t}^{-1}$ and $E\{\underline{t}\}=0$, we have with (3.19):

$$
\begin{equation*}
E\left\{\underline{t}^{*} \bar{Q}_{t}^{-1} B^{*} Q_{i} B \bar{Q}_{t}^{-1} \underline{t}\right\}=\operatorname{trace}\left(\bar{Q}_{t}^{-1} B^{*} Q_{i} B \bar{Q}_{t}^{-1} Q_{t}\right) \tag{3.54}
\end{equation*}
$$

or with

$$
\begin{align*}
Q_{t}= & \bar{Q}_{t}+\left(\sigma_{i}^{2}-1\right) B^{*} Q_{i} B  \tag{3.55}\\
E\left\{\underline{t}^{*} \bar{Q}_{t}^{-1} B^{*} Q_{i} B \bar{Q}_{t}^{-1} \underline{t}\right\} & =\operatorname{trace}\left(\bar{Q}_{t}^{-1} B^{*} Q_{i} B\right) \\
& +\left(\sigma_{i}^{2}-1\right) \operatorname{trace}\left(\bar{Q}_{t}^{-1} B^{*} Q_{i} B \bar{Q}_{t}^{-1} B^{*} Q_{i} B\right) \tag{3.56}
\end{align*}
$$

Substituting into (3.52) shows indeed that $E\left\{\underline{\hat{\sigma}}_{i}^{\prime 2}\right\}=\sigma_{i}^{2}$. Since the distribution of $\underline{\hat{\sigma}}_{i}^{\prime 2}$ is known under $H_{0}$ we can now perform the test: $\sigma_{i}^{2}=1$ versus $\sigma_{i}^{2} \neq 1$. Note by the way that $\hat{\sigma}_{i}^{2}$ and $\hat{\sigma}_{i}^{\prime 2}$ have identical distributions under $H_{0}$. By letting $i$ range from 1 to $p$, we can like in data snooping test whether additional variance-components are needed. They can also be done in an iterated way like in the iterated data snooping approach. In this context it is also interesting to investigate the form of the shifting variate of the linear models (2.8) and (3.40). We will return to this matter later on.

### 3.4 On the Connection of Two Point Fields

As an interesting application of the theory we have the problem of estimating and testing of the levels of precision of two pointfields which are to be connected. Let the coordinates of the two pointfields be collected in the vectors $\underline{x}_{i}, i=1,2$, of order $n \times 1$. We assume the $\underline{x}_{i}$ to be normally distributed with covariance matrices $\bar{\sigma}_{i}^{2} Q_{i}, i=1,2$. We also assume that $\underline{x}_{1}$ is independent of $\underline{x}_{2}$. The model reads then

$$
E\left\{\left[\begin{array}{l}
\underline{x}_{1}  \tag{3.57}\\
\underline{x}_{2}
\end{array}\right]\right\}=\left[\begin{array}{c}
I_{n} \\
I_{n}
\end{array}\right] x,\left[\begin{array}{cc}
\sigma_{1}^{2} Q_{1} & 0 \\
0 & \sigma_{2}^{2} Q_{2}
\end{array}\right]
$$

From this follows that matrix $B^{*}$ takes the form

$$
B^{*}=\left[\begin{array}{ll}
I_{n} & -I_{n} \tag{3.58}
\end{array}\right]
$$

and matrix $Q_{t}$ takes the form

$$
\begin{equation*}
Q_{t}=\sigma_{1}^{2} Q_{1}+\sigma_{2}^{2} Q_{2} \tag{3.59}
\end{equation*}
$$

Since we have two unknowns $\sigma_{1}^{2}$ and $\sigma_{2}^{2}$, the normal matrix $N_{\beta \alpha}$ is of order $2 \times 2$. With (2.63) we get for our case:

$$
\begin{align*}
& N_{11}=\frac{1}{2} \operatorname{trace}\left(Q_{1}\left[\sigma_{1}^{2} Q_{1}+\sigma_{2}^{2} Q_{2}\right]^{-1} Q_{1}\left[\sigma_{1}^{2} Q_{1}+\sigma_{2}^{2} Q_{2}\right]^{-1}\right) \\
& N_{12}=\frac{1}{2} \operatorname{trace}\left(Q_{1}\left[\sigma_{1}^{2} Q_{1}+\sigma_{2}^{2} Q_{2}\right]^{-1} Q_{2}\left[\sigma_{1}^{2} Q_{1}+\sigma_{2}^{2} Q_{2}\right]^{-1}\right)  \tag{3.60}\\
& N_{22}=\frac{1}{2} \operatorname{trace}\left(Q_{2}\left[\sigma_{1}^{2} Q_{1}+\sigma_{2}^{2} Q_{2}\right]^{-1} Q_{2}\left[\sigma_{1}^{2} Q_{1}+\sigma_{2}^{2} Q_{2}\right]^{-1}\right)
\end{align*}
$$

To simplify things, let us assume that $Q_{1}=Q_{2}$. The result (3.60) simplifies then to:

$$
\begin{align*}
& N_{11}=\frac{1}{2} n\left(\sigma_{1}^{2}+\sigma_{2}^{2}\right)^{-2} \\
& N_{12}=\frac{1}{2} n\left(\sigma_{1}^{2}+\sigma_{2}^{2}\right)^{-2}  \tag{3.61}\\
& N_{22}=\frac{1}{2} n\left(\sigma_{1}^{2}+\sigma_{2}^{2}\right)^{-2}
\end{align*}
$$

Hence, the normal matrix becomes singular! Thus if $Q_{1}=Q_{2}$ the two components $\sigma_{1}^{2}$ and $\sigma_{2}^{2}$ of model (3.57) are not separately estimable (this also makes sense). Later on we will consider the estimability problem for the general model (2.8). For the moment, let us change model (3.57) to overcome the estimability problem. Instead of (3.57) we take

$$
E\left\{\left[\begin{array}{l}
\underline{x}_{1}  \tag{3.62}\\
\underline{x}_{2}
\end{array}\right]\right\}=\left[\begin{array}{c}
I_{n} \\
I_{n}
\end{array}\right] x, \quad\left[\begin{array}{cc}
Q & 0 \\
0 & \sigma^{2} Q
\end{array}\right]
$$

Instead of (3.59) we then get

$$
\begin{equation*}
Q_{t}=\left(1+\sigma^{2}\right) Q \tag{3.63}
\end{equation*}
$$

We now have one unknown, $\sigma^{2}$, and are in the situation as described in Section 3. We therefore can apply formula (3.45). For our case we have:

$$
\begin{align*}
\underline{t}^{*} Q_{t}^{-1} B^{*} Q_{i} B Q_{t}^{-1} \underline{t} & =\left(1+\sigma^{2}\right)^{-2}\left(\underline{x}_{1}-\underline{x}_{2}\right)^{*} Q^{-1}\left(\underline{x}_{1}-\underline{x}_{2}\right) \\
\operatorname{trace}\left(B^{*} Q_{i} B Q_{t}^{-1}\right) & =\left(1+\sigma^{2}\right)^{-1} n  \tag{3.64}\\
\operatorname{trace}\left(B^{*} Q_{i} B Q_{t}^{-1} B^{*} Q_{i} B Q_{t}^{-1}\right) & =\left(1+\sigma^{2}\right)^{-2} n
\end{align*}
$$

Substituting (3.64) into (3.45) gives

$$
\begin{equation*}
\hat{\hat{\sigma}}^{2}=\sigma^{2}+\frac{\left(1+\sigma^{2}\right)^{-2}\left(\underline{x}_{1}-\underline{x}_{2}\right)^{*} Q^{-1}\left(\underline{x}_{1}-\underline{x}_{2}\right)-\left(1+\sigma^{2}\right)^{-1} n}{\left(1+\sigma^{2}\right)^{-2} n} \tag{3.65}
\end{equation*}
$$

or

$$
\begin{equation*}
\hat{\underline{\sigma}}^{2}=\frac{\left(\underline{x}_{1}-\underline{x}_{2}\right)^{*} Q^{-1}\left(\underline{x}_{1}-\underline{x}_{2}\right)}{n}-1 \tag{3.66}
\end{equation*}
$$

Application of (3.47) shows that $r=n$ and

$$
\begin{equation*}
\lambda_{1}=\lambda_{2}=\cdots=\lambda_{n}=\left(1+\sigma^{2}\right)^{-1} \tag{3.67}
\end{equation*}
$$

Hence,

$$
\begin{equation*}
\underline{\hat{\sigma}}^{2} \sim \sigma^{2}+\frac{\left(1+\sigma^{2}\right)^{-1} \chi^{2}(n, 0)-\left(1+\sigma^{2}\right)^{-1} n}{\left(1+\sigma^{2}\right)^{-2} n} \tag{3.68}
\end{equation*}
$$

or

$$
\begin{equation*}
\hat{\underline{\sigma}}^{2} \sim \frac{1+\sigma^{2}}{n} \chi^{2}(n, 0)-1 \tag{3.69}
\end{equation*}
$$

Note that $1+\underline{\sigma}^{2}$ is the estimator of the variance factor of unit weight in the model

$$
\begin{equation*}
E\left\{\underline{x}_{1}-\underline{x}_{2}\right\}=0, \quad\left(1+\sigma^{2}\right) Q \tag{3.70}
\end{equation*}
$$

Although the above example is a rather trivial one, it is of interest to elaborate the theory for the case of digitizing and connecting maps.

### 3.5 VCE and the $\underline{w}_{i}$-Test Statistics

Let us assume that the matrix $Q_{i}$ of section 3 takes the form

$$
Q_{i}=c_{i} c_{i}^{*}, \quad \text { with } c_{i}=\left[\begin{array}{lllll}
0 & \cdots & 0 & 1 & 0 \tag{3.71}
\end{array} \cdots 0\right]^{*}
$$

This implies that we want to estimate the variance $\sigma_{i}^{2}$ of one single observation. Since we have only one unknown variance-component, we can apply the result (3.45). Before doing this, we first note that in our case

$$
\begin{equation*}
Q_{t}=B^{*} \sum_{\alpha=1 \alpha \neq i}^{p} Q_{\alpha} B+\sigma_{i}^{2} B^{*} c_{i} c_{i}^{*} B \tag{3.72}
\end{equation*}
$$

This we write as

$$
\begin{equation*}
Q_{t}=\bar{Q}_{t}+\left(\sigma_{i}^{2}-1\right) B^{*} c_{i} c_{i}^{*} B \tag{3.73}
\end{equation*}
$$

with

$$
\begin{equation*}
\bar{Q}_{t}=\sum_{\alpha=1}^{p} B^{*} Q_{\alpha} B \tag{3.74}
\end{equation*}
$$

In (3.45) we need the inverse of $Q_{t}$. Using the matrix-identity

$$
\begin{equation*}
\left(A-B D^{-1} C\right)^{-1}=A^{-1}+A^{-1} B\left(D-C A^{-1} B\right)^{-1} C A^{-1} \tag{3.75}
\end{equation*}
$$

the inverse of (3.73) follows as

$$
\begin{equation*}
Q_{t}^{-1}=\bar{Q}_{t}^{-1}-\frac{\bar{Q}_{t}^{-1} B^{*} c_{i} c_{i}^{*} B \bar{Q}_{t}^{-1}}{\left(\sigma_{i}^{2}-1\right)^{-1}+c_{i}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{i}} \tag{3.76}
\end{equation*}
$$

Using this together with (3.71) enables us to write

$$
\begin{equation*}
\underline{t}^{*} Q_{t}^{-1} B^{*} Q_{i} B Q_{t}^{-1} \underline{t}=\left[\left(1-\frac{c_{i}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{i}}{\left(\sigma_{i}^{2}-1\right)^{-1}+c_{i}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{i}}\right)\left(c_{i}^{*} B \bar{Q}_{t}^{-1} \underline{t}\right)\right]^{2} \tag{3.77}
\end{equation*}
$$

In a similar way, we find

$$
\begin{equation*}
\operatorname{trace}\left(B^{*} Q_{i} B Q_{t}^{-1}\right)=\left[\left(1-\frac{c_{i}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{i}}{\left(\sigma_{i}^{2}-1\right)^{-1}+c_{i}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{i}}\right)\left(c_{i}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{i}\right)\right] \tag{3.78}
\end{equation*}
$$

and

$$
\begin{equation*}
\operatorname{trace}\left(B^{*} Q_{i} B Q_{t}^{-1} B^{*} Q_{i} B Q_{t}^{-1}\right)=\left[\left(1-\frac{c_{i}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{i}}{\left(\sigma_{i}^{2}-1\right)^{-1}+c_{i}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{i}}\right)\left(c_{i}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{i}\right)\right]^{2} \tag{3.79}
\end{equation*}
$$

Substitution of (3.77), (3.78) and (3.79) into (3.45) gives

$$
\begin{align*}
\hat{\underline{\sigma}}_{i}^{2} & =\sigma_{i}^{2}+\frac{\left(c_{i}^{*} B \bar{Q}_{t}^{-1} \underline{t}\right)^{2}}{\left(c_{i}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{i}\right)^{2}} \\
& -\left[\left(1-\frac{c_{i}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{i}}{\left(\sigma_{i}^{2}-1\right)^{-1}+c_{i}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{i}}\right)\left(c_{i}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{i}\right)\right]^{-1} \tag{3.80}
\end{align*}
$$

With

$$
\begin{equation*}
\left[\left(1-\frac{c_{i}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{i}}{\left(\sigma_{i}^{2}-1\right)^{-1}+c_{i}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{i}}\right)\left(c_{i}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{i}\right)\right]^{-1}=\left(\sigma_{i}^{2}-1\right)+\left(c_{i}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{i}\right)^{-1} \tag{3.81}
\end{equation*}
$$

equation (3.80) simplifies to

$$
\begin{equation*}
\hat{\underline{\sigma}}_{i}^{2}=1+\frac{\frac{\left(c_{i}^{*} B \bar{Q}_{t}^{-1} \underline{t}\right)^{2}}{c_{i}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{i}}-1}{c_{i}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{i}} \tag{3.82}
\end{equation*}
$$

Note that this estimator is independent of the unknown $\sigma_{i}^{2}$. We also note, that since our well-known $\underline{w}_{i}$-test statistics reads

$$
\begin{equation*}
\underline{w}_{i}=\frac{c_{i}^{*} B \bar{Q}_{t}^{-1} \underline{t}}{\left(c_{i}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{i}\right)^{1 / 2}} \tag{3.83}
\end{equation*}
$$

the result (3.82) can be written as

$$
\begin{equation*}
\hat{\underline{\sigma}}_{i}^{2}=1+\frac{\underline{w}_{i}^{2}-1}{c_{i}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{i}} \tag{3.84}
\end{equation*}
$$

This result also makes clear the sensitivity of the variance-component estimation for misspecifications in the functional model; a fact which also follows from the last theorem. With this theorem follows namely that if $E\{\underline{t}\} \neq 0$, then the variance-component estimators are distributed as a linear combination of non-central $\chi^{2}$-distributions. Finally note that we did not make use in the above derivation of the fact that $c_{i}=\left[\begin{array}{llllll}0 & \cdots & 0 & 1 & \cdots & 0\end{array}\right]^{*}$.

### 3.6 CoVCE and the $\underline{w}_{i}$-Test Statistics

Let us assume that we want to estimate the covariance between two observations, say observation $k$ and observation $l$. Matrix $Q_{i}$ of section 3 takes then the form

$$
Q_{i}=c_{k} c_{l}^{*}+c_{l} c_{k}^{*}, \quad \text { with } c_{k}=\left[\begin{array}{llllll}
0 & \cdots & 0 & 1 & 0 & \cdots \tag{3.85}
\end{array}\right]^{*}
$$

The unknown covariance $\sigma_{k l}$ can then be estimated according to (3.45) as

$$
\begin{equation*}
\underline{\hat{\sigma}}_{k l}=\sigma_{k l}+\frac{\underline{t}^{*} Q_{t}^{-1} B^{*} Q_{i} B Q_{t}^{-1} \underline{t}-\operatorname{trace}\left(B^{*} Q_{i} B Q_{t}^{-1}\right)}{\operatorname{trace}\left(B^{*} Q_{i} B Q_{t}^{-1} B^{*} Q_{i} B Q_{t}^{-1}\right)} \tag{3.86}
\end{equation*}
$$

where

$$
\begin{equation*}
Q_{t}=\bar{Q}_{t}+\sigma_{k l} B^{*}\left(c_{k} c_{l}^{*}+c_{l} c_{k}^{*}\right) B \tag{3.87}
\end{equation*}
$$

and $\bar{Q}_{t}$ is the covariance matrix of $\underline{t}$ in case $\sigma_{k l}=0$. Note that $\sigma_{k l}$ is allowed to be positive and negative. Hence the problem of negative variance components does not occur here. Also note that $\sigma_{k l}$ need not be the total covariance. That is, if a covariance between observations $k$ and $l$ is included in $\bar{Q}_{t}$, then $\sigma_{k l}$ of (3.87) should be interpreted as a perturbation or increment. The estimator $\hat{\sigma}_{k l}$ follows if we substitute (3.85) and (3.87) into (3.86). As it turns out however the result unfortunately depends on the unknown $\sigma_{k l}$. Instead of the optimal estimator $\underline{\hat{\sigma}}_{k l}$, we therefore take an approximate, but still unbiased, $\hat{\sigma}_{k l}^{\prime}$ by choosing $\sigma_{k l}=0$ in (3.86). This gives

$$
\begin{equation*}
\hat{\underline{\sigma}}_{k l}^{\prime}=\frac{\underline{t}^{*} \bar{Q}_{t}^{-1} B^{*} Q_{i} B \bar{Q}_{t}^{-1} \underline{t}-\operatorname{trace}\left(B^{*} Q_{i} B \bar{Q}_{t}^{-1}\right)}{\operatorname{trace}\left(B^{*} Q_{i} B \bar{Q}_{t}^{-1} B^{*} Q_{i} B \bar{Q}_{t}^{-1}\right)} \tag{3.88}
\end{equation*}
$$

With (3.85) we have

$$
\begin{aligned}
\underline{t}^{*} \bar{Q}_{t}^{-1} B^{*} Q_{i} B \bar{Q}_{t}^{-1} \underline{t} & =2\left(c_{k}^{*} B \bar{Q}_{t}^{-1} \underline{t}\right)\left(c_{l}^{*} B \bar{Q}_{t}^{-1} \underline{t}\right) \\
\operatorname{trace}\left(B^{*} Q_{i} B \bar{Q}_{t}^{-1}\right) & =2 c_{k}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{l} \\
\operatorname{trace}\left(B^{*} Q_{i} B \bar{Q}_{t}^{-1} B^{*} Q_{i} B \bar{Q}_{t}^{-1}\right) & =2\left(c_{k}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{l}\right)^{2}+2\left(c_{k}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{k}\right)\left(c_{l}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{l}\right)
\end{aligned}
$$

Substituting this into (3.88) gives

$$
\begin{equation*}
\underline{\hat{\sigma}}_{k l}^{\prime}=\frac{\left(c_{k}^{*} B \bar{Q}_{t}^{-1} \underline{t}\right)\left(c_{l}^{*} B \bar{Q}_{t}^{-1} \underline{t}\right)-c_{k}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{l}}{\left(c_{k}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{l}\right)^{2}+\left(c_{k}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{k}\right)\left(c_{l}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{l}\right)} \tag{3.89}
\end{equation*}
$$

Let us verify the unbiasedness of the estimator $\hat{\underline{\sigma}}_{k l}^{\prime}$. With (3.87) we have

$$
\begin{aligned}
E\left\{\left(c_{k}^{*} B \bar{Q}_{t}^{-1} \underline{t}\right)\left(c_{l}^{*} B \bar{Q}_{t}^{-1} \underline{t}\right)\right\} & =E\left\{\left(c_{k}^{*} B \bar{Q}_{t}^{-1} \underline{t t} \underline{Q}_{t}^{-1} B^{*} c_{l}\right)\right\}=c_{k}^{*} B \bar{Q}_{t}^{-1} Q_{t} \bar{Q}_{t}^{-1} B^{*} c_{l} \\
& =c_{k}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{l}+c_{k}^{*} B \bar{Q}_{t}^{-1}\left[\sigma_{k l} B^{*}\left(c_{k} c_{l}^{*}+c_{l} c_{k}^{*}\right) B\right] \bar{Q}_{t}^{-1} B^{*} c_{l} \\
& =c_{k}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{l}+\sigma_{k l}\left[\left(c_{k}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{l}\right)^{2}\right. \\
& \left.+\left(c_{k}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{k}\right)\left(c_{l}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{l}\right)\right]
\end{aligned}
$$

With this result and (3.89) it follows that indeed $E\left\{\underline{\hat{\sigma}}_{k l}^{\prime}\right\}=\sigma_{k l}$. If we use the abbreviation

$$
\begin{equation*}
n_{k l}=c_{k}^{*} B \bar{Q}_{t}^{-1} B^{*} c_{l} \tag{3.90}
\end{equation*}
$$

and remember that

$$
\begin{equation*}
\underline{w}_{k}=\frac{c_{k}^{*} B \bar{Q}_{t}^{-1} \underline{t}}{\sqrt{n_{k k}}} \tag{3.91}
\end{equation*}
$$

we can write (3.89) also as

$$
\begin{equation*}
\hat{\sigma}_{k l}^{\prime}=\frac{\underline{w}_{k} \underline{w}_{l}-\frac{n_{k l}}{\sqrt{n_{k k}} \sqrt{n_{l l}}}}{\frac{n_{k l}^{2}}{\sqrt{n_{k k}} \sqrt{n_{l l}}}+\sqrt{n_{k k}} \sqrt{n_{l l}}} \tag{3.92}
\end{equation*}
$$

Note that under the hypothesis that $\sigma_{k l}=0$, we have

$$
\begin{equation*}
E\left\{\underline{w}_{k} \underline{w}_{l}\right\}=\operatorname{Cov}\left\{\underline{w}_{k}, \underline{w}_{l}\right\}=\frac{n_{k l}}{\sqrt{n_{k k}} \sqrt{n_{l l}}}, \quad \text { if } \quad \sigma_{k l}=0 . \tag{3.93}
\end{equation*}
$$

This term equals the cosine of the angle between the two vectors $c_{k}$ and $c_{l}$ when projected with $P_{A}^{\perp}$. It is closely related to the error of the third kind. That is, if (3.93) is too large one will have difficulty in discriminating between two hypotheses $E\{\underline{t}\}=B^{*} c_{k} \nabla_{k}$ and $E\{\underline{t}\}=B^{*} c_{l} \nabla_{l}$.

## Chapter 4

## Estimating and Testing $\sigma_{1}^{2}$ and $\sigma_{2}^{2}$ in $\sigma_{0 i}^{2}=\sigma_{1}^{2}+\sigma_{2}^{2} x_{i}^{q}$ for EDM's

### 4.1 VCE from Repeated Measurements

According to the Least-Squares Estimators of the variance-components, $\sigma_{\alpha}^{2}, \alpha=1,2, \cdots, p$ in the model

$$
\begin{equation*}
E\{\underline{y}\}=A x, \quad E\left\{(\underline{y}-A x)(\underline{y}-A x)^{*}\right\}=\sum_{\alpha=1}^{p} \sigma_{\alpha}^{2} Q_{\alpha} \tag{4.1}
\end{equation*}
$$

are given as

$$
\left(\begin{array}{c}
\hat{\sigma}_{1}^{2}  \tag{4.2}\\
\underline{\hat{\sigma}}_{2}^{2} \\
\vdots \\
\hat{\sigma}_{p}^{2}
\end{array}\right)=\left[\begin{array}{cccc}
n_{11} & n_{12} & \cdots & n_{1 p} \\
n_{21} & n_{22} & \cdots & n_{2 p} \\
\vdots & \vdots & \ddots & \vdots \\
n_{p 1} & n_{p 2} & \cdots & n_{p p}
\end{array}\right]^{-1}\left[\begin{array}{c}
\frac{1}{2} \hat{e}^{*} Q_{y}^{-1} Q_{1} Q_{y}^{-1} \underline{\hat{e}} \\
\frac{1}{2} \hat{e}^{*} Q_{y}^{-1} Q_{2} Q_{y}^{-1} \underline{\hat{e}} \\
\vdots \\
\frac{1}{2} \underline{e}^{*} Q_{y}^{-1} Q_{p} Q_{y}^{-1} \underline{\hat{e}}
\end{array}\right]
$$

with:

$$
\begin{equation*}
n_{\beta \alpha}=\frac{1}{2} \operatorname{trace}\left(Q_{\beta} Q_{y}^{-1} P_{A}^{\perp} Q_{\alpha} Q_{y}^{-1} P_{A}^{\perp}\right) \tag{4.3}
\end{equation*}
$$

and with

$$
\begin{equation*}
Q_{y}=\sum_{\alpha=1}^{p} \sigma_{\alpha}^{2} Q_{\alpha} ; \quad P_{A}^{\perp}=I-A\left(A^{*} Q_{y}^{-1} A\right)^{-1} A^{*} Q_{y}^{-1} ; \quad \underline{\hat{e}}=P_{A}^{\perp} \underline{y} \tag{4.4}
\end{equation*}
$$

We will apply the above results to the model

$$
E\{\underline{y}\}=E\{\underbrace{\left[\begin{array}{c}
\underline{y}_{1}  \tag{4.5}\\
\underline{y}_{2} \\
\vdots \\
\underline{y}_{r}
\end{array}\right]}_{m r \times 1}\}=\underbrace{\left[\begin{array}{cccc}
e & 0 & \cdots & 0 \\
0 & e & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & e
\end{array}\right]}_{m r \times r} \underbrace{\left[\begin{array}{c}
x_{1} \\
x_{2} \\
\vdots \\
x_{r}
\end{array}\right]}_{r \times 1}, \quad Q_{y}=\underbrace{\left[\begin{array}{cccc}
\sigma_{01}^{2} I_{m} & 0 & \cdots & 0 \\
0 & \sigma_{02}^{2} I_{m} & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & \sigma_{0 r}^{2} I_{m}
\end{array}\right]}_{m r \times m r}
$$

with:

$$
e=\left[\begin{array}{llll}
1 & 1 & \cdots & 1 \tag{4.6}
\end{array}\right]^{*}, \quad \sigma_{0 i}^{2}=\sigma_{1}^{2}+\sigma_{2}^{2} x_{i}^{q}, i=1,2, \cdots, r
$$

Model (4.5) is valid for the case where one measures an $r$-number of unknown distances $x_{i}, i=$ $1,2, \cdots, r$, each an $m$-number of times. It is assumed that all the observations are uncorrelated.

Furthermore it is assumed that all the precision of the measurements is constant for a constant distance, but that it varies with the distance according to the law

$$
\begin{equation*}
\sigma_{0 i}^{2}=\sigma_{1}^{2}+\sigma_{2}^{2} x_{i}^{q}, i=1,2, \cdots, r \tag{4.7}
\end{equation*}
$$

where $q$ is an exponent of the distance which one can choose and $\sigma_{1}^{2}$ and $\sigma_{2}^{2}$ are the unknown variance-components which need to be estimated. Thus in our case we have two unknowns and the matrices $Q_{\alpha}, \alpha=1,2$ of (4.1) take the form

$$
Q_{1}=\underbrace{\left[\begin{array}{cccc}
I_{m} & 0 & \cdots & 0  \tag{4.8}\\
0 & I_{m} & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & I_{m}
\end{array}\right]}_{m r \times m r}, \quad Q_{2}=\underbrace{\left[\begin{array}{cccc}
x_{1}^{q} I_{m} & 0 & \cdots & 0 \\
0 & x_{2}^{q} I_{m} & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & x_{r}^{q} I_{m}
\end{array}\right]}_{m r \times m r}
$$

In order to apply (4.2) we need $P_{A}^{\perp}$ of (4.4). This matrix takes in our case a very simple form:

$$
P_{A}^{\perp}=\underbrace{\left[\begin{array}{cccc}
P_{e}^{\perp} & 0 & \cdots & 0  \tag{4.9}\\
0 & P_{e}^{\perp} & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & P_{e}^{\perp}
\end{array}\right]}_{m r \times m r}
$$

with $P_{e}^{\perp}=I_{m}-\frac{1}{m} e e^{*}$. Note that $P_{A}^{\perp}$ is independent of the $\sigma_{0 i}^{2}, i=1,2, \cdots, r$. Also note that the block matrices $P_{e}^{\perp}$ of $P_{A}^{\perp}$ correspond to the separate adjustment of each unknown distance. That is, per unknown distance we have an adjustment-problem with m-number of observations, one unknown distance and one variance-factor of unit weight $\sigma_{0 i}^{2}$. From adjustment theory we know that the variance factor of unit weight can be estimated rather straightforward. In our case the separate estimators of $\sigma_{0 i}^{2}, i=1,2, \cdots, r$ become

$$
\begin{equation*}
\underline{\hat{\sigma}}_{0 i}^{2}=\frac{\underline{y}_{i}^{*} P_{e}^{\perp} \underline{y}_{i}}{m-1} \text { with } \quad E\left\{\underline{\hat{\sigma}}_{0 i}^{2}\right\}=\sigma_{0 i}^{2}, \quad \sigma_{\sigma_{0 i}^{2}}^{2}=\frac{2 \sigma_{0 i}^{4}}{m-1}, i=1,2, \cdots, r \tag{4.10}
\end{equation*}
$$

This result may be used to perform a global test for each distance separately. It may also be used for obtaining a reasonable value for $m$, i.e., the number of measurements. Parallel to (4.10) we may also perform data snooping for each distance separately. The $w$-test statistics for the $k^{t h}$-observation in the $i^{t h}$-distance reads

$$
\begin{equation*}
\underline{w}_{k i}=\frac{\underline{y}_{k i}-\frac{1}{m} \sum_{l=1}^{m} \underline{y}_{l i}}{\sigma_{0 i} \sqrt{1-\frac{1}{m}}}, \quad i=1,2, \cdots, r, \quad k=1,2, \cdots, m \tag{4.11}
\end{equation*}
$$

Once the $r$-number of estimates $\hat{\sigma}_{0 i}^{2}$ of (4.10) are available, they may be used to get a first indication of whether law (4.7) holds or not. This may be done by plotting the $\hat{\sigma}_{0 i}^{2}$ against the $x_{i}^{q}$. Of course, $x_{i}$ is unknown, but here one can use the mean of the $m$-number of observed distances. The plot should then look something like:

By interpreting the estimates $\hat{\sigma}_{0 i}^{2}$ of (4.10) as observations, we can now with the help of (4.7) construct the following linear model of observation equations:

$$
E\left\{\left[\begin{array}{c}
\hat{\sigma}_{01}^{2}  \tag{4.12}\\
\hat{\sigma}_{02}^{2} \\
\vdots \\
\hat{\sigma}_{0 r}^{2}
\end{array}\right]\right\}=\left[\begin{array}{cc}
1 & x_{1}^{q} \\
1 & x_{2}^{q} \\
\vdots & \vdots \\
1 & x_{r}^{q}
\end{array}\right]\left[\begin{array}{c}
\sigma_{1}^{2} \\
\sigma_{2}^{2}
\end{array}\right], Q_{\hat{\sigma}_{0 i}^{2}}=\frac{2}{m-1} \underbrace{\left[\begin{array}{cccc}
\sigma_{01}^{4} & 0 & \cdots & 0 \\
0 & \sigma_{02}^{4} & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & \sigma_{0 r}^{4}
\end{array}\right]}_{r \times r}
$$

Note that because of our assumptions in (4.5), the $\hat{\sigma}_{0 i}^{2}$ are distributed as independent $\chi^{2}$-variables. The matrix $Q_{\hat{\sigma}_{0 i}^{2}}$ is therefore diagonal! In order to find estimators for $\sigma_{1}^{2}$ and $\sigma_{2}^{2}$ we can now apply all sorts of estimation principles (robust methods, maximum likelihood, least squares etc). We will solve (4.12) using the least-squares principle. The normal matrix of (4.12) reads

$$
N=\frac{m-1}{2}\left[\begin{array}{cc}
\sum_{i=1}^{r} \sigma_{0 i}^{-4} & \sum_{i=1}^{r} \sigma_{0 i}^{-4} x_{i}^{q}  \tag{4.13}\\
\sum_{i=1}^{r} \sigma_{0 i}^{-4} x_{i}^{q} & \sum_{i=1}^{r} \sigma_{0 i}^{-4} x_{i}^{2 q}
\end{array}\right]
$$

Its inverse reads

$$
N^{-1}=\frac{2}{m-1}\left[\left(\sum_{i=1}^{r} \sigma_{0 i}^{-4}\right)\left(\sum_{i=1}^{r} \sigma_{0 i}^{-4} x_{i}^{2 q}\right)-\left(\sum_{i=1}^{r} \sigma_{0 i}^{-4} x_{i}^{q}\right)^{2}\right]^{-1}\left[\begin{array}{cc}
\sum_{i=1}^{r} \sigma_{0 i}^{-4} x_{i}^{2 q} & -\sum_{i=1}^{r} \sigma_{0 i}^{-4} x_{i}^{q}  \tag{4.14}\\
-\sum_{i=1}^{r} \sigma_{0 i}^{-4} x_{i}^{q} & \sum_{i=1}^{r} \sigma_{0 i}^{-4}
\end{array}\right]
$$

The right-hand side of the normal equations reads:

$$
\underline{l}=\frac{m-1}{2}\left[\begin{array}{c}
\sum_{i=1}^{r} \sigma_{0 i}^{-4} \hat{\sigma}_{0 i}^{2}  \tag{4.15}\\
\sum_{i=1}^{r} \sigma_{0 i}^{-4} x_{i}^{q} \hat{\sigma}_{0 i}^{2}
\end{array}\right]
$$

With (4.14) and (4.15) the solution of (4.12) follows as

$$
\left[\begin{array}{l}
\hat{\sigma}_{1}^{2}  \tag{4.16}\\
\hat{\sigma}_{2}^{2}
\end{array}\right]=N^{-1} \underline{l}, \quad E\left\{\left[\begin{array}{l}
\hat{\sigma}_{1}^{2} \\
\hat{\sigma}_{2}^{2}
\end{array}\right]\right\}=\left[\begin{array}{c}
\sigma_{1}^{2} \\
\sigma_{2}^{2}
\end{array}\right], \quad D\left\{\left[\begin{array}{c}
\hat{\underline{\sigma}}_{1}^{2} \\
\hat{\sigma}_{2}^{2}
\end{array}\right]\right\}=N^{-1}
$$

We have now devised a two-step or phased procedure for estimating the variance-components $\sigma_{1}^{2}$ and $\sigma_{2}^{2}$. First (4.10) is used to compute the $\hat{\sigma}_{0 i}^{2}, i=1,2, \cdots, r$. Then in a second step the variancecomponents are computed according to (4.16). The solution so obtained is identical to the solution one gets when applying (4.2) and (4.5)!! Note that in the second step iterations are needed since the variances $\frac{2}{m-1} \sigma_{0 i}^{2}$ of (4.12) are unknown a-priori. In fact also the $x_{i}^{q}$ in the design matrix of (4.12) are unknown, but here it probably suffices to take the mean of the observed distances.

In order that the two estimators $\hat{\sigma}_{1}^{2}$ and $\hat{\sigma}_{2}^{2}$ are well-separated their correlation coefficient should be small enough. From (4.14) this correlation coefficient follows as

$$
\begin{equation*}
\rho_{12}=\frac{-\sum_{i=1}^{r} \sigma_{0 i}^{-4} x_{i}^{q}}{\sqrt{\sum_{i=1}^{r} \sigma_{0 i}^{-4} x_{i}^{2 q}} \sqrt{\sum_{i=1}^{r} \sigma_{0 i}^{-4}}} \tag{4.17}
\end{equation*}
$$

This correlation coefficient depends on the angle between the two column vectors of the design matrix of (4.12). More precisely: the correlation coefficient $\rho_{12}$ is small if the distances $x_{i}, i=$ $1,2, \cdots, r$ are chosen such that the angle between the two vectors

$$
\left[\begin{array}{c}
\sigma_{01}^{-2}  \tag{4.18}\\
\sigma_{02}^{-2} \\
\vdots \\
\sigma_{0 r}^{-2}
\end{array}\right] \text { and }\left[\begin{array}{c}
\sigma_{01}^{-2} x_{1}^{2} \\
\sigma_{01}^{-2} x_{2}^{2} \\
\vdots \\
\sigma_{01}^{-2} x_{r}^{2}
\end{array}\right]
$$

is large. Once the estimates $\hat{\sigma}_{1}^{2}$ and $\hat{\sigma}_{1}^{2}$ are computed, one can try to test their significance with respect to the values given by the manufacturer. If we denote the values given by the manufacturer as $\bar{\sigma}_{1}^{2}$ and $\bar{\sigma}_{2}^{2}$, the test statistic may take the form:

$$
\begin{equation*}
\underline{\nu}_{i}=\frac{\hat{\sigma}_{i}^{2}-\bar{\sigma}_{i}^{2}}{\sigma_{\hat{\sigma}_{i}^{2}}}, \quad i=1,2 \tag{4.19}
\end{equation*}
$$

Although the distribution of $\underline{\nu}_{i}$ is unknown, we may try the standard normal distribution as a crude approximation. With this approximation the test can be performed.

## Final Remarks

1. From the structure of (4.12) follows that it is not necessary to assume that the number of observation per unknown distance is constant.
2. The structure of model (4.12) resembles the 1-D Helmert-transformation $E\left\{\hat{\sigma}_{0 i}^{2}\right\}=\sigma_{1}^{2}+x_{i}^{q} \sigma_{2}^{2}$. If $x_{i}^{q}$ is considered to be stochastic, the model can be written in the form of the 1-D symmetric Helmert transformation $E\left\{\hat{\underline{\sigma}}_{0 i}^{2}\right\}=\sigma_{1}^{2}+E\left\{\underline{x}_{i}^{q}\right\} \sigma_{2}^{2}$. The solution method of (Teunissen: The 1and 2-D symmetric Helmert transformation, report 87.1, Delft) can then be applied.
3. Note that (4.12) may also be solved recursively. This may be of use if one wants to update the estimates of $\sigma_{1}^{2}$ and $\sigma_{2}^{2}$ if a new unknown distance is measured.

## Chapter 5

## Estimation and Testing of Covariance Matrices

### 5.1 Introduction

Consider the following two hypotheses:

$$
\begin{cases}H_{0}: & E\{\underline{y}\}=A x, \quad B^{*} x=b, \quad D\{\underline{y}\}=Q_{y}  \tag{5.1}\\ H_{A}: & E\{\underline{y}\}=A x, \quad D\{\underline{y}\}=Q_{y}\end{cases}
$$

We assume that $\underline{y}$ is normally distributed. The appropriate test statistic is then given by [see lecture notes MGII]:

$$
\left\{\begin{array}{l}
\underline{T}=\left[B^{*} \underline{\hat{x}}_{A}-b\right]^{*}\left(B^{*} Q_{\hat{x}_{A}} B\right)^{-1}\left[B^{*} \underline{\underline{x}}_{A}-b\right], \text { with }  \tag{5.2}\\
\underline{\hat{x}}_{A}=Q_{\hat{x}_{A}} A^{*} Q_{y}^{-1} \underline{y}, \quad Q_{\hat{x}_{A}}=\left(A^{*} Q_{y}^{-1} A\right)^{-1}
\end{array}\right.
$$

$\underline{T}$ has the following distribution:

$$
\begin{cases}H_{0}: & \underline{T} \sim \chi^{2}(b, 0)  \tag{5.3}\\ H_{A}: & \underline{T} \sim \chi^{2}(b, \lambda), \text { with } \lambda=\left[B^{*} x-b\right]^{*}\left(B^{*} Q_{y} B\right)^{-1}\left[B^{*} x-b\right]\end{cases}
$$

The test statistic $\underline{T}$ also follows from the Generalized Likelihood Ratio Test.
Note: $b=$ number of parameters under $H_{A}$ minus number of parameters under $H_{0}$.

### 5.2 The Model and Its Solution

As model we consider

$$
\begin{equation*}
E\{\underbrace{\underline{y}}_{r m \times 1}\}=\underbrace{\left(I_{r} \otimes A\right)}_{r m \times r n} \underbrace{x}_{r n \times 1}, \quad D\{\underline{y}\}=\underbrace{Q \otimes I_{m}}_{r m \times r m} \tag{5.4}
\end{equation*}
$$

According to [Teunissen, 1988]:

$$
\begin{equation*}
\underbrace{\frac{1}{2} \operatorname{tr}\left(Q_{\alpha} Q_{y}^{-1} P_{A}^{\perp} Q_{\beta} Q_{y}^{-1} P_{A}^{\perp}\right)}_{N_{\alpha \beta}} \hat{\sigma}_{\beta}^{2}=\underbrace{\frac{1}{2} \hat{e}^{*} Q_{y}^{-1} Q_{\alpha} Q_{y}^{-1} \hat{e}}_{l_{\alpha}} \tag{5.5}
\end{equation*}
$$

From (5.4) follows that

$$
\begin{equation*}
Q_{y}=Q \otimes I_{m}, \quad P_{A}=I_{r} \otimes A\left(A^{*} A\right)^{-1} A^{*}, \quad Q_{\alpha}=Q_{\alpha} \otimes I_{m} \tag{5.6}
\end{equation*}
$$

This gives

$$
\begin{aligned}
N_{\alpha \beta} & =\frac{1}{2} \operatorname{tr}\left(Q_{\alpha} \otimes I_{m} Q^{-1} \otimes I_{m} I_{r} \otimes P_{A}^{\perp} Q_{\beta} \otimes I_{m} Q^{-1} \otimes I_{m} I_{r} \otimes P_{A}^{\perp}\right) \\
& =\frac{1}{2} \operatorname{tr}\left(Q_{\alpha} Q^{-1} Q_{\beta} Q^{-1} \otimes P_{A}^{\perp}\right) \\
& =\frac{1}{2} \operatorname{tr}\left(Q_{\alpha} Q^{-1} Q_{\beta} Q^{-1}\right) \operatorname{tr}\left(P_{A}^{\perp}\right)
\end{aligned}
$$

or

$$
\begin{equation*}
N_{\alpha \beta}=\frac{1}{2}(m-n) \operatorname{tr}\left(Q_{\alpha} Q^{-1} Q_{\beta} Q^{-1}\right) \tag{5.7}
\end{equation*}
$$

In our case

$$
\hat{\sigma}^{2}=\left(\hat{\sigma}_{\beta}^{2}\right)=\left(\begin{array}{lllllllll}
\hat{\sigma}_{11} & \hat{\sigma}_{21} & \ldots & \hat{\sigma}_{r 1} & \hat{\sigma}_{22} & \ldots & \hat{\sigma}_{r 2} & \ldots & \hat{\sigma}_{r r} \tag{5.8}
\end{array}\right)^{*}
$$

We define the matrix $L$ as:

$$
\begin{equation*}
\underbrace{L}_{r^{2} \times r(r+1) / 2} \underbrace{\nabla(X)}_{r(r+1) / 2 \times 1}=\underbrace{\operatorname{vec}(X)}_{r^{2} \times 1} \text { for any symmetric } X_{r \times r} \text {. } \tag{5.9}
\end{equation*}
$$

Since the matrix $L$ has full rank $r(r+1) / 2$, it follows from (5.9) that

$$
\begin{equation*}
\nabla(X)=\left(L^{*} L\right)^{-1} L^{*} \operatorname{vec}(X) \text { for any symmetric } X \tag{5.10}
\end{equation*}
$$

With the projector $P\left[P \operatorname{vec}(X)=\operatorname{vec}(X)\right.$ for any $\left.X=X^{*}\right]$ and (5.9) follows that

$$
\begin{equation*}
P L \nabla(X)=P \operatorname{vec}(X)=\operatorname{vec}(X)=L \nabla(X) \text { for any } X^{*}=X \tag{5.11}
\end{equation*}
$$

and thus

$$
\begin{equation*}
P L=L \quad \text { or } \quad R(L) \subset R(P) \tag{5.12}
\end{equation*}
$$

Since $\operatorname{rank}(P)=\operatorname{rank}(L)=r(r+1) / 2$ or $\operatorname{dim}(R(P))=\operatorname{dim}(R(L))$ it follows with (5.12) that

$$
\begin{equation*}
R(P)=R(L) \tag{5.13}
\end{equation*}
$$

This shows, since $P$ is a projector that

$$
\begin{equation*}
P=L\left(L^{*} L\right)^{-1} L^{*} \tag{5.14}
\end{equation*}
$$

We will now derive the inverse of $\left(N_{\alpha \beta}\right)$. From (5.7) and (5.9) follows that

$$
\begin{aligned}
N_{\alpha \beta} & =\frac{1}{2}(m-n)\left(\operatorname{vec}\left(Q_{\alpha}\right)\right)^{*} Q^{-1} \otimes Q^{-1}\left(\operatorname{vec}\left(Q_{\beta}\right)\right) \\
& =\frac{1}{2}(m-n) \nabla\left(Q_{\alpha}\right)^{*} L^{*}\left(Q^{-1} \otimes Q^{-1}\right) L \nabla\left(Q_{\beta}\right)
\end{aligned}
$$

Note that $\nabla\left(Q_{\beta}\right)$ is the identity matrix of order $r(r+1) / 2$. Hence:

$$
\begin{equation*}
Q_{\nabla(\hat{Q})}=\left(N_{\alpha \beta}\right)^{-1}=\left[L^{*}\left(Q^{-1} \otimes Q^{-1}\right) L\right]^{-1} \frac{2}{m-n} \tag{5.15}
\end{equation*}
$$

or

$$
\begin{equation*}
L^{*}\left(Q^{-1} \otimes Q^{-1}\right) L Q_{\nabla(\hat{Q})}=\frac{2}{m-n} I \tag{5.16}
\end{equation*}
$$

or

$$
\begin{equation*}
\underbrace{L\left(L^{*} L\right)^{-1} L^{*}}_{P}\left(Q^{-1} \otimes Q^{-1}\right) L Q_{\nabla(\hat{Q})}=\frac{2}{m-n} L\left(L^{*} L\right)^{-1} \tag{5.17}
\end{equation*}
$$

or

$$
\begin{equation*}
\left(Q^{-1} \otimes Q^{-1}\right) P L Q_{\nabla(\hat{Q})}=\frac{2}{m-n} L\left(L^{*} L\right)^{-1} \tag{5.18}
\end{equation*}
$$

or

$$
\begin{equation*}
P L Q_{\nabla(\hat{Q})}=\frac{2}{m-n}(Q \otimes Q) L\left(L^{*} L\right)^{-1} \tag{5.19}
\end{equation*}
$$

or

$$
\begin{equation*}
\underbrace{Q_{\nabla(\hat{Q})}}_{r(r+1) / 2 \times r(r+1) / 2}=\frac{2}{m-n}\left(L^{*} L\right)^{-1} L^{*}(Q \otimes Q) L\left(L^{*} L\right)^{-1} \tag{5.20}
\end{equation*}
$$

From (5.5) and (5.6) follows that

$$
\begin{align*}
l_{\alpha} & =\frac{1}{2} y^{*} I_{r} \otimes P_{A}^{\perp} Q^{-1} \otimes I_{m} Q_{\alpha} \otimes I_{m} Q^{-1} \otimes I_{m} I_{r} \otimes P_{A}^{\perp} y \\
& =\frac{1}{2} y^{*}\left(Q^{-1} Q_{\alpha} Q^{-1} \otimes P_{A}^{\perp}\right) y \tag{5.21}
\end{align*}
$$

With $y=\sum_{i=1}^{r} e_{i} \otimes y_{i}=\sum_{i=1}^{r} \operatorname{vec}\left(y_{i} e_{i}^{*}\right)$ this gives

$$
\begin{align*}
l_{\alpha} & =\frac{1}{2}\left(v e c \sum_{i=1}^{r} y_{i} e_{i}^{*}\right)^{*}\left(Q^{-1} Q_{\alpha} Q^{-1} \otimes P_{A}^{\perp}\right)\left(v e c \sum_{j=1}^{r} y_{j} e_{j}^{*}\right) \\
& =\frac{1}{2} \operatorname{trace}\left[Q^{-1} Q_{\alpha} Q^{-1}\left(\sum_{j=1}^{r} y_{j} e_{j}^{*}\right)^{*} P_{A}^{\perp}\left(\sum_{i=1}^{r} y_{i} e_{i}^{*}\right)\right] \tag{5.22}
\end{align*}
$$

With $\underbrace{Y}_{m \times r}=\left[y_{1}, y_{2}, \ldots, y_{r}\right]=\sum_{i=1}^{r} y_{i} e_{i}^{*}$ this gives

$$
\begin{align*}
l_{\alpha} & =\frac{1}{2} \operatorname{trace}\left[Q^{-1} Q_{\alpha} Q^{-1} Y^{*} P_{A}^{\perp} Y\right] \\
& =\frac{1}{2}\left[\operatorname{vec}\left(Q^{-1} Q_{\alpha} Q^{-1}\right)\right]^{*}\left[\operatorname{vec} Y^{*} P_{A}^{\perp} Y\right]  \tag{5.23}\\
& =\frac{1}{2}\left[Q^{-1} \otimes Q^{-1} \operatorname{vec} Q_{\alpha}\right]^{*}\left[\operatorname{vec} Y^{*} P_{A}^{\perp} Y\right]
\end{align*}
$$

or

$$
\begin{equation*}
l_{\alpha}=\frac{1}{2} \operatorname{vec}\left(Q_{\alpha}\right)^{*} Q^{-1} \otimes Q^{-1} \operatorname{vec}\left(Y^{*} P_{A}^{\perp} Y\right) \tag{5.24}
\end{equation*}
$$

with $\operatorname{vec}\left(Q_{\alpha}\right)=L \nabla\left(Q_{\alpha}\right)=L$.Identity, this gives

$$
\begin{equation*}
l=\frac{1}{2} L^{*}\left(Q^{-1} \otimes Q^{-1}\right) L \nabla\left(Y^{*} P_{A}^{\perp} Y\right) \tag{5.25}
\end{equation*}
$$

From (5.20) and (5.25) follows that:

$$
\begin{align*}
\nabla(\hat{Q}) & =\frac{2}{m-n}\left(L^{*} L\right)^{-1} L^{*}(Q \otimes Q) L\left(L^{*} L\right)^{-1} \cdot \frac{1}{2} L^{*}\left(Q^{-1} \otimes Q^{-1}\right) L \nabla\left(Y^{*} P_{A}^{\perp} Y\right) \\
& =\frac{2}{m-n} \cdot \frac{1}{2}\left(L^{*} L\right)^{-1} L^{*}(Q \otimes Q) P\left(Q^{-1} \otimes Q^{-1}\right) L \nabla\left(Y^{*} P_{A}^{\perp} Y\right)  \tag{5.26}\\
& =\frac{1}{m-n}\left(L^{*} L\right)^{-1} L^{*} P L \nabla\left(Y^{*} P_{A}^{\perp} Y\right)
\end{align*}
$$

or

$$
\begin{equation*}
\underbrace{\hat{Q}}_{r \times r}=\frac{1}{m-n} Y^{*} P_{A}^{\perp} Y \tag{5.27}
\end{equation*}
$$

$\hat{Q}$ has a Wishart distribution. For later use it is important to know when $\nabla(\hat{Q})$ can be approximated by a normal distribution.

### 5.3 The Teststatistic \& Restrictions $B^{*} Q B=\phi_{0}$

The following two hypotheses will be considered:

$$
\begin{cases}H_{0}: & E\{\underline{y}\}=\left(I_{r} \otimes A\right) x,  \tag{5.28}\\ H_{A}: & D\{\underline{y}\}=Q \otimes I_{m}, \quad B^{*} Q B=\phi_{0} \\ \left.I_{r} \otimes A\right) x, & D\{\underline{y}\}=Q \otimes I_{m},\end{cases}
$$

The restrictions $B^{*} Q B=\phi_{0}$ can be written as $\operatorname{vec}\left(B^{*} Q B\right)=\operatorname{vec}\left(\phi_{0}\right)$ or as the linear restrictions

$$
\begin{equation*}
B^{*} \otimes B^{*} \operatorname{vec}(Q)=\operatorname{vec}\left(\phi_{0}\right) \tag{5.29}
\end{equation*}
$$

Since $Q$ is symmetric, (5.29) does not contain independent restrictions. Therefore

$$
\begin{equation*}
\left(B^{*} \otimes B^{*}\right) L_{r} \nabla Q=L_{p} \nabla \phi_{0} \tag{5.30}
\end{equation*}
$$

or

$$
\begin{equation*}
\left(L_{p}^{*} L_{p}\right)^{-1} L_{p}^{*}\left(B^{*} \otimes B^{*}\right) L_{r} \nabla Q=\nabla \phi_{0} \tag{5.31}
\end{equation*}
$$

The teststatistic [see (5.2)] follows then as:

$$
\begin{align*}
\underline{T}= & \left.L_{p}^{+}\left(B^{*} \otimes B^{*}\right) L_{r} \nabla(\hat{Q})-\nabla \phi_{0}\right]^{*}\left[L_{p}^{+}\left(B^{*} \otimes B^{*}\right) L_{r} Q_{\nabla(\hat{Q})} L_{r}(B \otimes B) L_{p}^{+*}\right]^{-1}  \tag{5.32}\\
& {\left[L_{p}^{+}\left(B^{*} \otimes B^{*}\right) L_{r} \nabla(\hat{Q}) \nabla \phi_{0}\right] } \tag{5.33}
\end{align*}
$$

This gives with (5.20):

$$
\begin{aligned}
\underline{T}= & \frac{m-n}{2}\left[L_{p}^{+}\left(B^{*} \otimes B^{*}\right) L_{r} \nabla(\hat{Q})-\nabla\left(\phi_{0}\right)\right]^{*}\left[L_{p}^{+}\left(B^{*} \otimes B^{*}\right) P_{r} Q \otimes Q P_{r}(B \otimes B) L_{p}^{+*}\right]^{-\frac{1}{r}}(5.34) \\
& {\left[L_{p}^{+}\left(B^{*} \otimes B^{*}\right) L_{r} \nabla(\hat{Q}) \nabla\left(\phi_{0}\right)\right] }
\end{aligned}
$$

with

$$
\begin{aligned}
P_{r} & =\frac{1}{2}\left[I_{r^{2}}+K_{r r}\right] \\
K_{r r}(B \otimes B) & =(B \otimes B) K_{p p} \\
P_{r}(B \otimes B) & =(B \otimes B) P_{p}
\end{aligned}
$$

follows from (5.35) that

$$
\begin{align*}
\underline{T}= & \frac{m-n}{2}\left[L_{p}^{+}\left(B^{*} \otimes B^{*}\right) L_{r} \nabla(\hat{Q})-\nabla\left(\phi_{0}\right)\right]^{*}\left[L_{p}^{+}\left(B^{*} Q B \otimes B^{*} Q B\right) L_{p}^{+*}\right]^{-1}  \tag{5.35}\\
& {\left[L_{p}^{+}\left(B^{*} \otimes B^{*}\right) L_{r} \nabla(\hat{Q}) \nabla\left(\phi_{0}\right)\right] }
\end{align*}
$$

Since

$$
\begin{equation*}
\left[L_{p}^{+}\left(B^{*} Q B \otimes B^{*} Q B\right) L_{p}^{+*}\right]^{-1}=L_{p}^{*}\left(B^{*} Q B\right)^{-1} \otimes\left(B^{*} Q B\right)^{-1} L_{p} \tag{5.36}
\end{equation*}
$$

and

$$
\begin{equation*}
\nabla\left(\phi_{0}\right)=L_{p}^{+}\left(B^{*} \otimes B^{*}\right) L_{r} \nabla\left(Q_{0}\right) \tag{5.37}
\end{equation*}
$$

Equation (5.36) can be written as

$$
\begin{array}{r}
\underline{T}=\frac{m-n}{2}\left[\nabla\left(\hat{Q}-Q_{0}\right)^{*} L_{r}(B \otimes B) L_{p}^{+*} L_{p}^{*}\left(B^{*} Q B\right)^{-1}\right.  \tag{5.38}\\
\left.\otimes\left(B^{*} Q B\right)^{-1} L_{p} L_{p}^{+}\left(B^{*} \otimes B^{*}\right) L_{r} \nabla\left(\hat{Q}-Q_{0}\right)\right]
\end{array}
$$

or as

$$
\begin{align*}
\underline{T} & =\frac{m-n}{2}\left[\nabla\left(\hat{Q}-Q_{0}\right)^{*} L_{r}^{*}\left[B\left(B^{*} Q B\right)^{-1} B^{*}\right] \otimes\left[B\left(B^{*} Q B\right)^{-1} B^{*}\right] L_{r} \nabla\left(\hat{Q}-Q_{0}\right)\right. \\
& =\frac{m-n}{2}\left[\operatorname{vec}\left(\hat{Q}-Q_{0}\right)\right]^{*}\left[B\left(B^{*} Q B\right)^{-1} B^{*}\right] \otimes\left[B\left(B^{*} Q B\right)^{-1} B^{*}\right]\left[\operatorname{vec}\left(\hat{Q}-Q_{0}\right)\right]  \tag{5.39}\\
& =\frac{m-n}{2} \operatorname{trace}\left[B\left(B^{*} Q B\right)^{-1} B^{*}\left(\hat{Q}-Q_{0}\right) B\left(B^{*} Q B\right)^{-1} B^{*}\left(\hat{Q}-Q_{0}\right)\right] \\
& =\frac{m-n}{2} \operatorname{trace}\left[\left(B^{*} Q B\right)^{-1}\left(B^{*} \hat{Q} B-B^{*} Q_{0} B\right)\left(B^{*} Q B\right)^{-1}\left(B^{*} \hat{Q} B-B^{*} Q_{0} B\right)\right]
\end{align*}
$$

Under $H_{0}$ we have $B^{*} Q B=B^{*} Q_{0} B=\phi_{0}$. Thus under $H_{0}$ we get

$$
\begin{equation*}
T_{H_{0}}=\frac{m-n}{2} \operatorname{trace}\left[\left[\left(B^{*} Q_{0} B\right)^{-1}\left(B^{*} \hat{Q} B\right)-I_{p}\right]\left[\left(B^{*} Q_{0} B\right)^{-1}\left(B^{*} \hat{Q} B\right)-I_{p}\right]\right] \tag{5.40}
\end{equation*}
$$

with

$$
\begin{equation*}
|B^{*} \underline{\hat{Q}} B-\underline{\hat{\lambda}_{i}} \overbrace{B^{*} Q_{0} B}^{\phi_{0}}|=0, i=1,2, \ldots, p \tag{5.41}
\end{equation*}
$$

We may write (5.40) also as

$$
\begin{equation*}
\underline{T}_{H_{0}}=\frac{m-n}{2} \sum_{i=1}^{p}\left(\underline{\underline{\lambda}}_{i}-1\right)^{2} \tag{5.42}
\end{equation*}
$$

Since the difference in the number of parameters between $H_{A}$ and $H_{0}$ is $r(r+1) / 2-\{r(r+1) / 2-$ $p(p+1) / 2\}$, the form of the teststatistic suggests that $I_{H_{0}}$ is approximately distributed as

$$
\begin{equation*}
H_{0}: \underline{T}_{H_{0}} \sim \chi^{2}(p(p+1) / 2,0) \tag{5.43}
\end{equation*}
$$

### 5.4 A Comparison with the Restricted Generalized Likelihood Ratio Test

If we define $\underline{t}=\left(I_{r} \otimes B^{*}\right) \underline{y}$ [do not confuse this B , with B of section 3], with $B^{*} A=0$, it follows from (5.4) that

$$
\begin{equation*}
\underbrace{E\{\underline{t}\}}_{r(m-n) \times 1}=0, \quad D\{\underline{t}\}=\underbrace{Q}_{r \times r} \otimes \underbrace{B^{*} B}_{(m-n) \times(m-n)} \tag{5.44}
\end{equation*}
$$

The following hypotheses will be considered

$$
\begin{equation*}
H_{0}^{\prime}: D\{\underline{t}\}=Q_{0} \otimes B^{*} B, \quad H_{A}^{\prime}: D\{\underline{t}\}=Q \otimes B^{*} B \tag{5.45}
\end{equation*}
$$

The restricted likelihood function reads then

$$
\begin{equation*}
\log \rho_{\underline{t}}(t / Q)=-\frac{1}{2} \log 2 \pi-\frac{1}{2} \log \left|Q \otimes B^{*} B\right|-\frac{1}{2} t^{*} Q^{-1} \otimes\left(B^{*} B\right)^{-1} t \tag{5.46}
\end{equation*}
$$

From this follows that

$$
\begin{align*}
-2 \log \frac{\rho_{\underline{t}}\left(t / Q_{0}\right)}{\rho_{\underline{t}}(t / \hat{Q})} & =\log \left|Q_{0} \hat{Q}^{-1} \otimes I_{m-n}\right|+t^{*}\left[\left(Q_{0}^{-1}-\hat{Q}^{-1}\right) \otimes\left(B^{*} B\right)\right] t \\
& =(m-n) \log \left|Q_{0} \hat{Q}^{-1}\right|+y^{*}\left[\left(Q_{0}^{-1}-\hat{Q}^{-1}\right) \otimes P_{B}\right] y \tag{5.47}
\end{align*}
$$

With $y=\sum_{i=1}^{r} e_{i} \otimes y_{i}=\sum_{i}^{r} \operatorname{vec}\left(y_{i} e_{i}^{*}\right)$ this gives

$$
\begin{align*}
-2 \log \frac{\rho_{\underline{t}}\left(t / Q_{0}\right)}{\rho_{\underline{t}}(t / \hat{Q})} & =(m-n) \log \left|Q_{0} \hat{Q}^{-1}\right|+\left(\operatorname{vec} \sum_{i=1}^{r} y_{i} e_{i}^{*}\right)^{*}\left[\left(Q_{0}^{-1}-\hat{Q}^{-1}\right) \otimes P_{B}\right]\left(\operatorname{vec} \sum_{i=1}^{r} y_{i} e_{i}^{*}\right) \\
& =(m-n) \log \left|Q_{0} \hat{Q}^{-1}\right|+\operatorname{trace}\left[\left(Q_{0}^{-1}-\hat{Q}^{-1}\right) \sum_{j=1}^{r} y_{j} e_{j}^{*} P_{B} \sum_{i}^{r} y_{i} e_{i}^{*}\right] \\
& =(m-n) \log \left|Q_{0} \hat{Q}^{-1}\right|+\operatorname{trace}\left[\left(Q_{0}^{-1}-\hat{Q}^{-1}\right) Y^{*} P_{A}^{\perp} Y\right]  \tag{5.48}\\
& =(m-n)\left\{\log \left|Q_{0} \hat{Q}^{-1}\right|+\operatorname{trace}\left[Q_{0}^{-1} \hat{Q}-I\right]\right\} \\
& =-(m-n)\left\{\log \left|Q_{0}^{-1} \hat{Q}\right|+\operatorname{trace}\left[I-Q_{0}^{-1} \hat{Q}\right]\right\}
\end{align*}
$$

Hence

$$
\begin{equation*}
-2 \log \frac{\rho_{\underline{t}}\left(t / Q_{0}\right)}{\rho_{\underline{t}}(t / \hat{Q})}=-(m-n)\left\{\sum_{i=1}^{r} \log \underline{\hat{\lambda}}_{i}+\sum_{i=1}^{r}\left(1-\underline{\hat{\lambda}}_{i}\right)\right\} \tag{5.49}
\end{equation*}
$$

Substitution of

$$
\begin{equation*}
\log \underline{\hat{\lambda}}_{i}=\log 1+\left(\underline{\hat{\lambda}}_{i}-1\right)-\frac{1}{2}\left(\underline{\hat{\lambda}}_{i}-1\right)^{2}+\ldots \tag{5.50}
\end{equation*}
$$

into (5.49) shows that

$$
\begin{equation*}
-2 \log \frac{\rho_{\underline{t}}\left(t / Q_{0}\right)}{\rho_{\underline{t}}(t / \hat{Q})} \doteq \frac{m-n}{2} \sum_{i=1}^{r}\left(\hat{\underline{\lambda}}_{i}-1\right)^{2}=I_{H_{0}} \tag{5.51}
\end{equation*}
$$

### 5.5 The Teststatistic and Restrictions $B^{*} Q C=0$

The following two hypotheses will be considered:

$$
\left\{\begin{array}{lll}
H_{0}: & E\{\underline{y}\}=\left(I_{r} \otimes A\right) x & D\{\underline{y}\}=Q \otimes I_{m} \tag{5.52}
\end{array} \quad B^{*} Q C=0\right.
$$

The restriction $B^{*} Q C=0$ can be written as $\operatorname{vec}\left(B^{*} Q C\right)=\operatorname{vec}(Q)=0$ or as the linear restrictions:

$$
\begin{equation*}
\left(C^{*} \otimes B^{*}\right) \operatorname{vec}(Q)=0 \text { or }\left(C^{*} \otimes B^{*}\right) L_{r} \nabla(Q)=0 \tag{5.53}
\end{equation*}
$$

The teststatistic [see (5.2)] follows then as:

$$
\begin{equation*}
\underline{T}=\frac{m-n}{2}\left[C^{*} \otimes B^{*} \operatorname{vec}(\hat{Q})\right]^{*}\left[C^{*} \otimes B^{*} P_{r} Q \otimes Q P_{r} C \otimes B\right]^{-1}\left[C^{*} \otimes B^{*} v e c(\hat{Q})\right] \tag{5.54}
\end{equation*}
$$

with

$$
\begin{cases}P_{r}=\frac{1}{2}\left(I_{r^{2}+K_{r r}}\right) & P_{r} Q \otimes Q P_{r}=Q \otimes Q P_{r}  \tag{5.55}\\ K_{r r}(C \otimes B)=(B \otimes C) K_{p q} & \end{cases}
$$

follows from (5.54) that

$$
\begin{equation*}
\underline{T}=\frac{m-n}{2}\left[C^{*} \otimes B^{*} \operatorname{vec}(\hat{Q})\right]^{*}\left[C^{*} \otimes B^{*} Q \otimes Q\left\{\frac{1}{2} C \otimes B+\frac{1}{2} B \otimes C K_{p q}\right\}\right]^{-1}\left[C^{*} \otimes B^{*} v e c(\hat{Q})\right] \tag{5.56}
\end{equation*}
$$

or

$$
\begin{equation*}
\underline{T}=(m-n)\left[C^{*} \otimes B^{*} \operatorname{vec}(\hat{Q})\right]^{*}\left[C^{*} Q C \otimes B^{*} Q B+C^{*} Q B \otimes B^{*} Q C K_{p q}\right]^{-1}\left[C^{*} \otimes B^{*} v e c(\hat{Q})\right] \tag{5.57}
\end{equation*}
$$

Therefore, under $H_{0}$ :

$$
\begin{align*}
\underline{T}_{H_{0}} & =(m-n) \operatorname{vec}(\hat{Q})^{*} C \otimes B\left(C^{*} Q C\right)^{-1} \otimes\left(B^{*} Q B\right)^{-1} C^{*} \otimes B^{*} \operatorname{vec}(\hat{Q}) \\
& =(m-n) \operatorname{vec}(\hat{Q})^{*} C\left(C^{*} Q C\right)^{-1} C^{*} \otimes B\left(B^{*} Q B\right)^{-1} B^{*} \operatorname{vec}(\hat{Q})  \tag{5.58}\\
& =(m-n) \operatorname{trace}\left[C\left(C^{*} Q C\right)^{-1} C^{*} \hat{Q} B\left(B^{*} Q B\right)^{-1} B^{*} \hat{Q}\right]
\end{align*}
$$

or

$$
\begin{equation*}
\underline{T}_{H_{0}}=(m-n) \operatorname{trace}\left[\left(C^{*} Q C\right)^{-1} C^{*} \hat{Q} B\left(B^{*} Q B\right)^{-1} B^{*} \hat{Q} C\right] \tag{5.59}
\end{equation*}
$$

The form of (5.54) suggests that

$$
\begin{equation*}
H_{0}: \underline{T}_{H_{0}} \sim \chi^{2}(p q, 0) \tag{5.60}
\end{equation*}
$$

## Chapter 6

## A New Method for Estimating and Testing the Substitute Matrix $H$

### 6.1 The Generalized Eigenvalue Problem

Let $\underline{x}$ be a random $n$-vector with variance matrix $Q_{x}$. Let $H_{x}$ be a substitute (or criterion) matrix. The precision of $\underline{x}$ is then said to satisfy the criterion if

$$
\begin{equation*}
a^{*} Q_{x} a \leq a^{*} H_{x} a \quad \forall a \in R^{n} \tag{6.1}
\end{equation*}
$$

or if

$$
\begin{equation*}
\frac{a^{*} Q_{x} a}{a^{*} H_{x} a} \leq 1, \forall a \in R^{n} \tag{6.2}
\end{equation*}
$$

since

$$
\begin{equation*}
\max _{a \in R^{n}} \frac{a^{*} Q_{x} a}{a^{*} H_{x} a}=\lambda_{\max } \tag{6.3}
\end{equation*}
$$

where $\lambda_{\max }$ is the maximum eigenvalue of the generalized eigenvalue problem

$$
\begin{equation*}
\left|Q_{x}-\lambda H_{x}\right|=0 \tag{6.4}
\end{equation*}
$$

it follows that (6.2) is equivalent to

$$
\begin{equation*}
\lambda_{\max } \leq 1 \tag{6.5}
\end{equation*}
$$

### 6.2 Invariance of $\lambda$

An advantage of the generalized eigenvalue problem approach is that the eigenvalues of (6.4) are independent of the chosen S-system. We will prove the following theorem:

## Theorem:

The non-zero eigenvalues of $\left|H_{x} A^{*} Q_{y}^{-1} A-\mu I\right|=0$ are the reciprocals of the non-zero eigenvalues of $\left|Q_{x}^{S}-\lambda H_{x}^{S}\right|=0$, where

$$
\begin{aligned}
Q_{x}^{S} & =S\left[S^{*} A^{*} Q_{y}^{-1} A S\right]^{-1} S^{*}, \quad R^{n}=R(S) \oplus N(A) \\
H_{x}^{S} & =P_{R(S), N(A)} H_{x} P_{R(S), N(A)}^{*} \\
P_{R(S), N(A)} & =S\left(V_{0}^{*} S\right)^{-1} V_{0}^{*}=I-V_{1}\left[\left(S^{\perp}\right)^{*} V_{1}\right]^{-1}\left(S^{\perp}\right)^{*}
\end{aligned}
$$

and

$$
R\left(V_{1}\right)=N(A), \quad R\left(V_{0}\right)=N(A)^{\perp}, \quad R\left(S^{\perp}\right)=R(S)^{\perp}
$$

## Proof:

$$
\begin{equation*}
\left|H_{x} A^{*} Q_{y}^{-1} A-\mu I\right|=\left|H_{x} V_{0}\left(S^{*} V_{0}\right)^{-1} S^{*} A^{*} Q_{y}^{-1} A-\mu I\right|=0 \tag{6.6}
\end{equation*}
$$

Since

$$
\left[\begin{array}{c}
\left(V_{0}^{*} S\right)^{-1} V_{0}^{*}  \tag{6.7}\\
{\left[\left(S^{\perp}\right)^{*} V_{1}\right]^{-1}\left(S^{\perp}\right)^{*}}
\end{array}\right]\left[S: V_{1}\right]=\left[\begin{array}{ll}
I & 0 \\
0 & I
\end{array}\right]
$$

we get

$$
\begin{align*}
0 & =\left|\left[\begin{array}{cc}
{\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} H_{x} V_{0}\left(S^{*} V_{0}\right)^{-1} S^{*} A^{*} Q_{y}^{-1} A S-\mu I\right]} & 0 \\
{\left[\left(S^{\perp}\right)^{*} V_{1}\right]^{-1}\left(S^{\perp}\right)^{*} H_{x} V_{0}\left(S^{*} V_{0}\right)^{-1} S^{*} A^{*} Q_{y}^{-1} A S} & -\mu I
\end{array}\right]\right| \\
& =\left|\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} H_{x} V_{0}\left(S^{*} V_{0}\right)^{-1} S^{*} A^{*} Q_{y}^{-1} A S-\mu I\right]\right||-\mu I| \text { for } \mu \neq 0 \tag{6.8}
\end{align*}
$$

This gives with $\lambda=\frac{1}{\mu}$ :

$$
\begin{aligned}
0 & =\left|\left[S^{*} A^{*} Q_{y}^{-1} A S\right]^{-1}-\lambda\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} H_{x} V_{0}\left(S^{*} V_{0}\right)^{-1}\right| \\
& =\left|\left[\begin{array}{cc}
V_{0}^{*} S\left[S^{*} A^{*} Q_{y}^{-1} A S\right]^{-1} S^{*} V_{0}-\lambda V_{0}^{*} H_{x} V_{0} & 0 \\
0 & \lambda I
\end{array}\right]\right| \\
& =\left|\left[\begin{array}{c}
V_{0}^{*} \\
S^{\perp *}
\end{array}\right]\left[S\left[S^{*} A^{*} Q_{y}^{-1} A S\right]^{-1} S^{*}-\lambda S\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} H_{x} V_{0}\left(S^{*} V_{0}\right)^{-1} S^{*}\right]\left[V_{0} \vdots S^{\perp}\right]\right| \\
& =\left|Q_{x}^{S}-\lambda H_{x}^{S}\right|
\end{aligned}
$$

### 6.3 The Alberda-Baarda Substitute Martix

For a two dimensional planar geodetic network, the Alberda-Baarda substitute matrix takes the form
$H_{x}=\left[\begin{array}{cccc}{\left[\begin{array}{cccc}d^{2}+\Delta d_{1}^{2} & d^{2}-d_{12}^{2} & \cdots & d^{2}-d_{1 n}^{2} \\ d^{2}-d_{21}^{2} & d^{2}+\Delta d_{2}^{2} & \cdots & d^{2}-d_{2 n}^{2} \\ \vdots & \vdots & \ddots & \vdots \\ d^{2}-d_{n 1}^{2} & d^{2}-d_{n 2}^{2} & \cdots & d^{2}+\Delta d_{n}^{2}\end{array}\right]} & & \\ & 0 & & \\ & & & \\ & & & \\ & {\left[\begin{array}{cccc}d^{2}+\Delta d_{1}^{2} & d^{2}-d_{12}^{2} & \cdots & d^{2}-d_{1 n}^{2} \\ d^{2}-d_{21}^{2} & d^{2}+\Delta d_{2}^{2} & \cdots & d^{2}-d_{2 n}^{2} \\ \vdots & \vdots & \ddots & \vdots \\ d^{2}-d_{n 1}^{2} & d^{2}-d_{n 2}^{2} & \cdots & d^{2}+\Delta d_{n}^{2}\end{array}\right]}\end{array}\right]$
where

- $d^{2}$ disappears when $H_{x}$ is formulated in an S-system
- $\Delta d_{i}^{2}$ is a parameter per point $i$
- $d_{i j}^{2}$ is a function of the relative positions of points $i$ and $j$, e.g. $d_{i j}^{2}=c_{0}+c_{1} l_{i j}$

Remark: $\quad c_{0}, c_{1}$, and $\Delta d_{i}^{2}$ can be considered parameters $\theta$ in $H_{x}(\theta)$.

### 6.4 A LSQ-Approach for Estimating $\theta$ in $H_{x}(\theta)$

Our objective is to estimate $\theta$ such that the difference $Q_{x}-H_{x}(\theta)$ is minimal in a least-squares sense. We formulate the following linearized model of observation equations:

$$
\begin{equation*}
E\left\{\operatorname{vec}\left[Q_{x}-H_{x}\left(\theta_{0}\right)\right]\right\}=\operatorname{vec}\left(\partial_{\alpha} H_{x}\left(\theta_{0}\right) \Delta \theta^{\alpha}\right) \tag{6.10}
\end{equation*}
$$

Note: both $Q_{x}$ and $H_{x}(\theta)$ should be defined in the same S-system.
We will take the unit matrix as weight matrix. Then, according to Teunissen [1988] the system of normal equations reads:

$$
\begin{equation*}
\frac{1}{2} \operatorname{tr}\left[\partial_{\beta} H_{x}\left(\theta_{0}\right)\right] \Delta \hat{\theta}^{\beta}=\frac{1}{2} \operatorname{tr}\left[\partial_{\alpha} H_{x}\left(\theta_{0}\right) \partial_{\beta} H_{x}\left(\theta_{0}\right)\left[Q_{x}-H_{x}\left(\theta_{0}\right)\right]\right] \tag{6.11}
\end{equation*}
$$

If the model is linear:

$$
\begin{equation*}
H_{x}(\theta)=\sum_{\alpha} H_{\alpha} \theta^{\alpha} \tag{6.12}
\end{equation*}
$$

We get instead of (6.11):

$$
\begin{equation*}
\frac{1}{2} \operatorname{tr}\left[H_{\alpha} H_{\beta}\right] \hat{\theta}^{\beta}=\frac{1}{2} \operatorname{tr}\left[H_{\alpha} Q_{x}\right] \tag{6.13}
\end{equation*}
$$

A disadvantages of the above procedure is that $\hat{\theta}^{\beta}$ is not independent of the chosen S-system.

### 6.5 Our Proposal

Let $\underline{\hat{x}}$ be the least-squares solution to

$$
\begin{equation*}
E\{\underline{y}\}=A x \quad D\{\underline{y}\}=Q_{y} \tag{6.14}
\end{equation*}
$$

and define

$$
\begin{equation*}
\Delta \underline{x}=\underline{\hat{x}}-E\{\underline{\hat{x}}\} \tag{6.15}
\end{equation*}
$$

Then:

$$
\begin{equation*}
E\left\{\Delta \underline{x} \Delta \underline{x}^{*}\right\}=Q_{\hat{x}} \tag{6.16}
\end{equation*}
$$

Although (6.16) holds we will consider the model

$$
\begin{equation*}
E\left\{\Delta \underline{x} \Delta \underline{x}^{*}\right\}=H_{x}(\theta) \tag{6.17}
\end{equation*}
$$

Note: both $Q_{\hat{x}}$ and $H_{x}(\theta)$ in the same S -system.
This gives after linearization

$$
\begin{equation*}
E\left\{\operatorname{vec}\left[\Delta \underline{x} \Delta \underline{x}^{*}-H_{x}\left(\theta_{0}\right)\right]\right\}=\operatorname{vec}\left(\partial_{\alpha} H_{x}\left(\theta_{0}\right)\right) \Delta \theta^{\alpha} \tag{6.18}
\end{equation*}
$$

Taking the inverse of (6.16) as weight matrix, application of our theory gives:

$$
\begin{equation*}
\frac{1}{2} \operatorname{tr}\left[\partial_{\alpha} H_{x}\left(\theta_{0}\right) Q_{\hat{x}}^{-1} \partial_{\beta} H_{x}\left(\theta_{0}\right) Q_{\hat{x}}^{-1}\right] \Delta \hat{\hat{\theta}}^{\beta}=\frac{1}{2} \operatorname{tr}\left[\partial_{\alpha} H_{x}\left(\theta_{0}\right) Q_{\hat{x}}^{-1}\left[\Delta \underline{x} \Delta \underline{x}^{*}-H_{x}\left(\theta_{0}\right)\right] Q_{\hat{x}}^{-1}\right] \tag{6.19}
\end{equation*}
$$

Unfortunately this result cannot be used since $\Delta \underline{x} \Delta \underline{x}^{*}$ is unknown in general. However, its expectation $E\left\{\Delta \underline{x} \Delta \underline{x}^{*}\right\}$ is known [see (6.16)]. We therefore propose to replace $\Delta \underline{x} \Delta \underline{x}^{*}$ in (6.19) by its expectation $Q_{\hat{x}}$ [This is not an unusual procedure; think of eccentrincity errors and Kalman filtering]. We then get instead of (6.19):

$$
\begin{equation*}
\frac{1}{2} \operatorname{tr}\left[\partial_{\alpha} H_{x}\left(\theta_{0}\right) Q_{\hat{x}}^{-1} \partial_{\beta} H_{x}\left(\theta_{0}\right) Q_{\hat{x}}^{-1}\right] \Delta \hat{\hat{\theta}}^{\beta}=\frac{1}{2} \operatorname{tr}\left[\partial_{\alpha} H_{x}\left(\theta_{0}\right) Q_{\hat{x}}^{-1}\left[Q_{\hat{x}}-H_{x}\left(\theta_{0}\right)\right] Q_{\hat{x}}^{-1}\right] \tag{6.20}
\end{equation*}
$$

If the model is linear:

$$
\begin{equation*}
H_{x}(\theta)=\sum_{\alpha} H_{\alpha} \theta^{\alpha} \tag{6.21}
\end{equation*}
$$

we get instead of (6.20):

$$
\begin{equation*}
\frac{1}{2} \operatorname{tr}\left[H_{\alpha} Q_{\hat{x}}^{-1} H_{\beta} Q_{\hat{x}}^{-1}\right] \hat{\theta}^{\beta}=\frac{1}{2} \operatorname{tr}\left[H_{\alpha} Q_{\hat{x}}^{-1}\right] \tag{6.22}
\end{equation*}
$$

Compare this results with (6.13). The above described method has the following advantages:

- All the least-squares diagnostics can be applied.
- No generalized eigenvalue problem needs to be solved for.
- The estimate $\hat{\theta}^{\beta}$ is independent of the chosen S-system. This can be seen as follows. Let $R$ be a square and regular matrix. Then:

$$
\begin{aligned}
\operatorname{tr}\left[R H_{\alpha} R^{*}\left[R Q_{\hat{x}} R^{*}\right]^{-1} R H_{\beta} R^{*}\left[R Q_{\hat{x}} R^{*}\right]^{-1}\right] & =\operatorname{tr}\left[H_{\alpha} Q_{\hat{x}}^{-1} H_{\beta} Q_{\hat{x}}^{-1}\right] \\
\operatorname{tr}\left[R H_{\alpha} R^{*}\left[R Q_{\hat{x}} R^{*}\right]^{-1}\right] & =\operatorname{tr}\left[H_{\alpha} Q_{\hat{x}}^{-1}\right]
\end{aligned}
$$

The normal matrix $\frac{1}{2} \operatorname{tr}\left[H_{\alpha} N H_{\beta} N\right]$ is singular if and only if there exist $x^{\alpha}, \alpha=1,2, \ldots, n$ such that:

$$
\begin{equation*}
\frac{1}{2} x^{\alpha} \operatorname{tr}\left[H_{\alpha} N H_{\beta} N\right] x^{\beta}=0 \tag{6.23}
\end{equation*}
$$

or

$$
\begin{equation*}
\frac{1}{2} \operatorname{tr}\left[H_{\alpha} x^{\alpha} N H_{\beta} x^{\beta} N\right]=0 \tag{6.24}
\end{equation*}
$$

If $\lambda_{i}, i=1,2, \ldots, n$ are the eigenvalues of $H_{\alpha} x^{\alpha} N$ then

$$
\begin{equation*}
\frac{1}{2} \operatorname{tr}\left[H_{\alpha} x^{\alpha} N H_{\beta} x^{\beta} N\right]=\sum_{i=1}^{n} \lambda_{i}^{2} \tag{6.25}
\end{equation*}
$$

Hence, (6.24) can only be true if

$$
\begin{equation*}
\lambda_{i}=0 \quad \forall i=1,2, \ldots, n \tag{6.26}
\end{equation*}
$$

or if

$$
\begin{equation*}
H_{\alpha} x^{\alpha} N=0 \tag{6.27}
\end{equation*}
$$

For instance: $\exists x^{\alpha}$ such that $R\left(H_{\alpha} x^{\alpha}\right) \subset N(N)$
Example A closed levelling loop with 3 observations.

$$
N=\left(\begin{array}{rrr}
2 & -1 & -1  \tag{6.28}\\
-1 & 2 & -1 \\
-1 & -1 & 2
\end{array}\right) \quad \Delta d^{2} H_{1}=\left(\begin{array}{ccc}
\Delta d^{2} & 0 & 0 \\
0 & \Delta d^{2} & 0 \\
0 & 0 & \Delta d^{2}
\end{array}\right) c_{1} H_{2}=\left(\begin{array}{rrr}
0 & -c_{1} \ell & -c_{1} \ell \\
-c_{1} \ell & 0 & -c_{1} \ell \\
-c_{1} \ell & -c_{1} \ell & 0
\end{array}\right)(6.2
$$

Remark: This singularity does not occur in the set up of 6.4.
No S-transformation needs to be applied a priori. This can be seen as follows: Substitution of

$$
\begin{equation*}
H_{\alpha}:=\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} H_{\alpha} V_{0}\left(S^{*} V_{0}\right)^{-1} \text { and } Q_{\hat{x}}^{-1}:=S^{*} A^{*} Q_{y}^{-1} A S \tag{6.29}
\end{equation*}
$$

into (15) gives

$$
\begin{array}{r}
\frac{1}{2} \operatorname{tr}\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} H_{\alpha} V_{0}\left(S^{*} V_{0}\right)^{-1} \cdot S^{*} A^{*} Q_{y}^{-1} A S\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} H_{\beta} V_{0}\left(S^{*} V_{0}\right)^{-1} \cdot S^{*} A^{*} Q_{y}^{-1} A S\right] \hat{\theta}_{\beta}= \\
\frac{1}{2} \operatorname{tr}\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} H_{\alpha} V_{0}\left(S^{*} V_{0}\right)^{-1} \cdot S^{*} A^{*} Q_{y}^{-1} A S\right] \tag{6.30}
\end{array}
$$

or

$$
\begin{equation*}
\frac{1}{2} \operatorname{tr}\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} H_{\alpha} A^{*} Q_{y}^{-1} A H_{\beta} A^{*} Q_{y}^{-1} A S\right] \hat{\theta}_{\beta}=\frac{1}{2} \operatorname{tr}\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} H_{\alpha} A^{*} Q_{y}^{-1} A S\right] \tag{6.31}
\end{equation*}
$$

or

$$
\begin{equation*}
\frac{1}{2} \operatorname{tr}\left[H_{\alpha} A^{*} Q_{y}^{-1} A H_{\beta} A^{*} Q_{y}^{-1} A\right] \hat{\theta}_{\beta}=\frac{1}{2} \operatorname{tr}\left[H_{\alpha} A^{*} Q_{y}^{-1} A\right] \tag{6.32}
\end{equation*}
$$

Note that $Q_{\hat{x}}$ is not needed explicitly. Only the (reduced) normal matrix $A^{*} Q_{y}^{-1} A$ is needed.

Remark: It has been assumed that the normal matrix is invertible.

Remark: In practice one will have $H_{x}(\theta)=H_{0}+\sum H_{\alpha} \theta^{\alpha}$ instead of $H_{x}(\theta)=\sum H_{\alpha} \theta^{\alpha}$.
Remark: In the special case that $H_{x}(\theta)=H \theta$ we get

$$
\begin{equation*}
\hat{\theta}=\frac{\sum_{i} \lambda_{i}}{\sum_{i} \lambda_{i}^{2}} \tag{6.33}
\end{equation*}
$$

If $\hat{\theta}=1$ then the precision test is accepted. with:

$$
\begin{equation*}
\left|H A^{*} Q_{y}^{-1} A-\lambda_{i} I\right|=0 \tag{6.34}
\end{equation*}
$$

If we write this as $\left|\left(A^{*} Q_{y}^{-1} A\right)^{-}-\mu_{i} H\right|=0,(6.33)$ becomes

$$
\begin{equation*}
\hat{\theta}=\frac{\sum_{i} \frac{1}{\mu_{i}}}{\sum_{i} \frac{1}{\mu_{i}^{2}}} \tag{6.35}
\end{equation*}
$$

From this follows that:

$$
\begin{equation*}
\hat{\theta}=\frac{\frac{1}{\mu_{\max }}\left[\sum_{i} \frac{\mu_{\max }}{\mu_{i}}\right]}{\frac{1}{\mu_{\max }^{2}}\left[\sum_{i} \frac{\mu_{\max }^{2}}{\mu_{i}^{2}}\right]}<\mu_{\max } \tag{6.36}
\end{equation*}
$$

since

$$
\begin{equation*}
\left[\sum_{i} \frac{\mu_{\max }^{2}}{\mu_{i}^{2}}\right]>\left[\sum_{i} \frac{\mu_{\max }}{\mu_{i}}\right] \tag{6.37}
\end{equation*}
$$

Thus:

$$
\begin{equation*}
\hat{\theta}<\mu_{\max } \tag{6.38}
\end{equation*}
$$

Remark: With (6.32) one can still study partial networks instead of the total network. In this case one needs the reduced normal matrix.

Remark: If one considers instead of $\Delta \underline{x}$ the (estimable) linear functions $B^{*} \Delta \underline{x}$, then (6.22) should be replaced by:

$$
\begin{equation*}
\frac{1}{2} \operatorname{tr}\left[B^{*} H_{\alpha} B\left[B^{*} Q_{\hat{x}} B\right]^{-1} B^{*} H_{\beta} B\left[B^{*} Q_{\hat{x}} B\right]^{-1}\right] \hat{\theta}^{\beta}=\frac{1}{2} \operatorname{tr}\left[B^{*} H_{\alpha} B\left[B^{*} Q_{\hat{x}} B\right]^{-1}\right] \tag{6.39}
\end{equation*}
$$

### 6.6 On the Teststatistics $\underline{T}_{m-n} \& \underline{w}$

According to previous section, the solution of the minimization problem

$$
\begin{equation*}
\min _{\theta} T(\theta) \tag{6.40}
\end{equation*}
$$

with

$$
\begin{equation*}
T(\theta)=\left[\operatorname{vec}\left(Q_{x}-H_{\alpha} \theta^{\alpha}\right)\right]^{*} Q_{x}^{-1} \otimes Q_{x}^{-1}\left[\operatorname{vec}\left(Q_{x}-H_{\alpha} \theta^{\alpha}\right)\right] \tag{6.41}
\end{equation*}
$$

is given by

$$
\begin{equation*}
\hat{\theta}^{\beta}=\left[\operatorname{tr}\left(H_{\alpha} Q_{x}^{-1} H_{\beta} Q_{x}^{-1}\right)\right]^{-1} \operatorname{tr}\left(H_{\alpha} Q_{x}^{-1}\right) \tag{6.42}
\end{equation*}
$$

If we use the notation

$$
\begin{equation*}
\hat{H}=H_{\alpha} \hat{\theta}^{\alpha} \tag{6.43}
\end{equation*}
$$

it follows with (6.41) that:

$$
\begin{equation*}
T(\hat{\theta})=\left[\operatorname{vec}\left(Q_{x}-\hat{H}\right)\right]^{*} Q_{x}^{-1} \otimes Q_{x}^{-1}\left[\operatorname{vec}\left(Q_{x}-\hat{H}\right)\right] \tag{6.44}
\end{equation*}
$$

with the property:

$$
\begin{equation*}
\operatorname{tr}(A B C D)=\operatorname{vec}(D)^{*}\left(A \otimes C^{*}\right) \operatorname{vec}\left(B^{*}\right) \tag{6.45}
\end{equation*}
$$

we may write (6.44) as

$$
\begin{equation*}
T(\hat{\theta})=\operatorname{tr}\left[Q_{x}^{-1}\left(Q_{x}-\hat{H}\right) Q_{x}^{-1}\left(Q_{x}-\hat{H}\right)\right] \tag{6.46}
\end{equation*}
$$

or as

$$
\begin{equation*}
T(\hat{\theta})=\operatorname{tr}\left[\left(I-Q_{x}^{-1} \hat{H}\right)\left(I-Q_{x}^{-1} \hat{H}\right)\right]=\sum_{i=1}^{n}\left(1-\hat{\lambda}_{i}\right)^{2} \tag{6.47}
\end{equation*}
$$

where $\hat{\lambda}_{i}, i=1,2, \ldots, n$ are the eigenvalues of

$$
\begin{equation*}
\left|Q_{x}-\hat{\lambda}_{i} \hat{H}\right|=0 \tag{6.48}
\end{equation*}
$$

Although expression (6.47) looks already rather simple, it can be simplified still a bit further. From (6.47) follows that

$$
\begin{equation*}
T(\hat{\theta})=\operatorname{tr}\left[I_{n}-2 Q_{x}^{-1} \hat{H}+Q_{x}^{-1} \hat{H} Q_{x}^{-1} \hat{H}\right]=n-2 \operatorname{tr}\left(Q_{x}^{-1} \hat{H}\right)+\operatorname{tr}\left(Q_{x}^{-1} \hat{H} Q_{x}^{-1} \hat{H}\right) \tag{6.49}
\end{equation*}
$$

Substitution of (6.43) gives

$$
\begin{equation*}
T(\hat{\theta})=n-2 \operatorname{tr}\left(Q_{x}^{-1} H_{\alpha}\right) \hat{\theta}^{\alpha}+\hat{\theta}^{\alpha} \operatorname{tr}\left(Q_{x}^{-1} H_{\alpha} Q_{x}^{-1} H_{\beta}\right) \hat{\theta}^{\beta} \tag{6.50}
\end{equation*}
$$

But according to (6.42):

$$
\begin{equation*}
\operatorname{tr}\left(Q_{x}^{-1} H_{\alpha} Q_{x}^{-1} H_{\beta}\right) \hat{\theta}^{\beta}=\operatorname{tr}\left(H_{\alpha} Q_{x}^{-1}\right) \tag{6.51}
\end{equation*}
$$

Substitution of (6.51) into (6.50) gives:

$$
\begin{equation*}
T(\hat{\theta})=n-2 \operatorname{tr}\left(Q_{x}^{-1} H_{\alpha}\right) \hat{\theta}^{\alpha}+\operatorname{tr}\left(H_{\alpha} Q_{x}^{-1}\right) \hat{\theta}^{\alpha} \tag{6.52}
\end{equation*}
$$

From this follows that:

$$
\begin{align*}
T(\hat{\theta}) & =n-\operatorname{tr}\left(Q_{x}^{-1} H_{\alpha}\right) \hat{\theta}^{\alpha} \\
& =n-\operatorname{tr}\left(Q_{x}^{-1} \hat{H}\right)  \tag{6.53}\\
& =n-\sum_{i=1}^{n} \hat{\lambda}_{i} \tag{6.54}
\end{align*}
$$

Remark: For leveling networks one should take $n$ of (6.54) equal to $n-1$, and for 2D planer networks one should take $n$ of (6.54) equal to $2 n-4$.

Remark: In the special case that $H(\theta)=H \theta$, we have $\hat{\theta}=\sum_{i} \lambda_{i} / \sum_{i} \lambda_{i}^{2}$, with $\left|Q_{x}^{-1} H-\lambda I\right|=0$, and therefore

$$
\begin{equation*}
T(\hat{\theta})=n-\frac{\left(\sum_{i} \lambda_{i}\right)^{2}}{\left(\sum_{i} \lambda_{i}^{2}\right)} \tag{6.55}
\end{equation*}
$$

Remark: Note that we may write

$$
\begin{equation*}
\operatorname{tr}\left[Q_{x}^{-1} \hat{H}\right]=\operatorname{tr}\left[A^{*} Q_{y}^{-1} A \hat{H}\right]=\operatorname{tr}\left[A \hat{H} A^{*} Q_{y}^{-1}\right] \tag{6.56}
\end{equation*}
$$

If $\hat{H}$ is close to $Q_{x}$, then $A \hat{H} A^{*} Q_{y}^{-1}$ is close to $P_{A}$, and we know that $\operatorname{tr}\left(P_{A}\right)=n$.

Remark: A comparison of (6.47) and (6.54) shows that $\sum_{i=1}^{n} \hat{\lambda}_{i}=\sum_{i=1}^{n} \hat{\lambda}_{i}^{2}$ or $\operatorname{tr}\left(Q_{x}^{-1} \hat{H}\right)=$ $\operatorname{tr}\left(Q_{x}^{-1} \hat{H} Q_{x}^{-1} \hat{H}\right)$.

Remark: Expression (6.47) [but not (6.54)] can probably be used for testing the precision. Let $H=H_{\alpha} \theta^{\alpha}$ be the criterion matrix with $\alpha=1,2, \ldots, p$. The following criterion may then be useful:

$$
\begin{equation*}
\frac{\operatorname{tr}\left[\left(I-Q_{x}^{-1} H\right)\left(I-Q_{x}^{-1} H\right)\right]}{n(n+1) / 2-p} \doteq 1 \tag{6.57}
\end{equation*}
$$

We will now derive the equivalent of the $w$-teststatistic. We have

$$
\begin{array}{r}
c_{y_{i}}^{*} Q_{y}^{-1} Q_{\hat{e}} Q_{y}^{-1} c_{y_{i}}=\left[\operatorname{vec}\left(e_{i} e_{j}^{*}+e_{j} e_{i}^{*}\right)\right]^{*}\left[Q_{x}^{-1} \otimes Q_{x}^{-1}-\left(Q_{x}^{-1} \otimes Q_{x}^{-1}\right) \operatorname{vec}\left(H_{\alpha}\right)\right. \\
\left.\left(\operatorname{tr}\left[Q_{x}^{-1} H_{\beta} Q_{x}^{-1} H_{\alpha}\right]\right)^{-1} \operatorname{vec}\left(H_{\beta}\right)^{*}\left(Q_{x}^{-1} \otimes Q_{x}^{-1}\right)\right]\left[\operatorname{vec}\left(e_{i} e_{j}^{*}+e_{j} e_{i}^{*}\right)\right] \tag{6.58}
\end{array}
$$

or

$$
\begin{array}{r}
c_{y_{i}}^{*} Q_{y}^{-1} Q_{\hat{e}} Q_{y}^{-1} c_{y_{i}}=\operatorname{tr}\left[Q_{x}^{-1}\left(e_{i} e_{j}^{*}+e_{j} e_{i}^{*}\right) Q_{x}^{-1}\left(e_{i} e_{j}^{*}+e_{j} e_{i}^{*}\right)\right]-\operatorname{tr}\left[Q_{x}^{-1} H_{\alpha} Q_{x}^{-1}\left(e_{i} e_{j}^{*}+e_{j} e_{i}^{*}\right)\right] \\
\left.\operatorname{tr}\left(Q_{x}^{-1} H_{\beta} Q_{x}^{-1} H_{\alpha}\right)\right]^{-1} \operatorname{tr}\left[Q_{x}^{-1}\left(e_{i} e_{j}^{*}+e_{j} e_{i}^{*}\right) Q_{x}^{-1} H_{\beta}\right] \tag{6.59}
\end{array}
$$

or

$$
\begin{gather*}
c_{y_{i}}^{*} Q_{y}^{-1} Q_{\hat{e}} Q_{y}^{-1} c_{y_{i}}=2\left(e_{j}^{*} Q_{x}^{-1} e_{i}\right)^{2}+2 e_{i}^{*} Q_{x}^{-1} e_{i} e_{j}^{*} Q_{x}^{-1} e_{j}- \\
4\left[e_{j}^{*} Q_{x}^{-1} H_{\alpha} Q_{x}^{-1} e_{i}\right]\left[\operatorname{tr}\left(Q_{x}^{-1} H_{\beta} Q_{x}^{-1} H_{\alpha}\right)\right]^{-1}\left[e_{j}^{*} Q_{x}^{-1} H_{\beta} Q_{x}^{-1} e_{i}\right] \tag{6.60}
\end{gather*}
$$

and

$$
\begin{align*}
c_{y_{i}}^{*} Q_{y}^{-1} \hat{e} & =\left[\operatorname{vec}\left(e_{i} e_{j}^{*}+e_{j} e_{i}^{*}\right)\right]^{*} Q_{x}^{-1} \otimes Q_{x}^{-1}\left[\operatorname{vec}\left(Q_{x}-H_{\alpha} \hat{\theta}^{\alpha}\right)\right] \\
& =\operatorname{tr}\left[Q_{x}^{-1}\left(Q_{x}-H_{\alpha} \hat{\theta}^{\alpha}\right) Q_{x}^{-1}\left(e_{i} e_{j}^{*}+e_{j} e_{i}^{*}\right)\right] \\
& =2 e_{j}^{*}\left(I-H_{\alpha} \hat{\theta}^{\alpha} Q_{x}^{-1}\right) e_{i}  \tag{6.61}\\
& =2 \delta_{i j}-2 e_{i}^{*} Q_{x}^{-1} H_{\alpha} \hat{\theta}^{\alpha} e_{j}
\end{align*}
$$

From (6.60) and (6.62) follows that:

$$
\begin{equation*}
w=\frac{\delta_{i j}-e_{i}^{*} Q_{x}^{-1} H_{\alpha} \hat{\theta}^{\alpha} e_{j}}{s} \tag{6.62}
\end{equation*}
$$

with

$$
\begin{array}{r}
s=\left[\left(e_{j}^{*} Q_{x}^{-1} e_{i}\right)^{2}+e_{i}^{*} Q_{x}^{-1} e_{i} e_{j}^{*} Q_{x}^{-1} e_{j}-2\left[e_{j}^{*} Q_{x}^{-1} H_{\alpha} Q_{x}^{-1} e_{i}\right]\right. \\
\left.\left[\operatorname{tr}\left(Q_{x}^{-1} H_{\beta} Q_{x}^{-1} H_{\alpha}\right)\right]^{-1}\left[e_{j}^{*} Q_{x}^{-1} H_{\beta} Q_{x}^{-1} e_{i}\right]\right]^{1 / 2} \tag{6.63}
\end{array}
$$

Remark: This result can possibly be used for testing whether individual elements of $Q_{x}$ are close enough to the corresponding elements of $H_{\alpha} \hat{\theta}^{\alpha}$.

Wrong! The correct answer is:

$$
\begin{equation*}
w=\frac{a^{*}\left[Q_{x}^{-1}-Q_{x}^{-1} \hat{H} Q_{x}^{-1}\right] a}{\left[\left(a^{*} Q_{x}^{-1} a\right)^{2}-\left(a^{*} Q_{x}^{-1} H_{\alpha} Q_{x}^{-1} a\right)\left(\operatorname{tr}\left[Q_{x}^{-1} H_{\beta} Q_{x}^{-1} H_{\alpha}\right]\right)^{-1}\left(a^{*} Q_{x}^{-1} H_{\beta} Q_{x}^{-1} a\right)\right]^{1 / 2}} \tag{6.64}
\end{equation*}
$$

or with $\bar{a}=Q_{x}^{-1} a$ :

$$
\begin{equation*}
w=\frac{\bar{a}^{*}\left[Q_{x}-\hat{H}\right] \bar{a}}{\left[\left(\bar{a}^{*} Q_{x} \bar{a}\right)^{2}-\left(\bar{a}^{*} H_{\alpha} \bar{a}\right)\left(\operatorname{tr}\left[Q_{x}^{-1} H_{\beta} Q_{x}^{-1} H_{\alpha}\right]\right)^{-1}\left(\bar{a}^{*} H_{\beta} \bar{a}\right)\right]^{1 / 2}} \tag{6.65}
\end{equation*}
$$

Note that the equation (6.65) can also be written as:

$$
\begin{equation*}
w=\frac{\frac{\bar{a}^{*} Q_{x} \bar{a}}{\bar{a}^{*} \hat{H} \bar{a}}-1}{\left[\left(\frac{\bar{a}^{*} Q_{x} \bar{a}}{\bar{a}^{*} \hat{H} \bar{a}}\right)^{2}-\frac{\bar{a}^{*} H_{\alpha} \bar{a}}{\bar{a}^{*} \hat{H} \bar{a}}\left(\operatorname{tr}\left[Q_{x}^{-1} H_{\beta} Q_{x}^{-1} H_{\alpha}\right]\right)^{-1} \frac{\bar{a}^{*} H_{\alpha} \bar{a}}{\bar{a}^{*} \hat{H} \bar{a}}\right]^{1 / 2}} \tag{6.66}
\end{equation*}
$$

If we use the approximation

$$
\begin{equation*}
\left.\left.w=\frac{c_{y}^{*} Q_{y}^{-1} \hat{e}}{\left(c_{y}^{*} Q_{y}^{-1} Q_{\hat{e}} Q_{y}^{-1} c_{y}\right.}\right)^{1 / 2} \doteq \frac{c_{y}^{*} Q_{y}^{-1} \hat{e}}{\left(c_{y}^{*} Q_{y}^{-1} c_{y}\right.}\right)^{1 / 2} \tag{6.67}
\end{equation*}
$$

Then equation (6.66) reduces to

$$
\begin{equation*}
w \doteq 1-\frac{\bar{a}^{*} \hat{H} \bar{a}}{\bar{a}^{*} Q_{x} \bar{a}} \tag{6.68}
\end{equation*}
$$

Hence:

$$
\begin{equation*}
w_{\max } \doteq 1-\frac{1}{\lambda_{\max }} \tag{6.69}
\end{equation*}
$$

### 6.7 On the Choice of a Scaled Unit Weight Matrix

According to previous subsections, the following holds:

$$
\begin{equation*}
\frac{1}{2} \operatorname{tr}\left[H_{\alpha} Q_{x}^{-1} H_{\beta} Q_{x}^{-1}\right] \hat{\theta}^{\beta}=\frac{1}{2} \operatorname{tr}\left[H_{\alpha} Q_{x}^{-1} \Delta \underline{x} \Delta \underline{x}^{*} Q_{x}^{-1}\right] \tag{6.70}
\end{equation*}
$$

where both $H$ and $Q_{x}$ are in the same S-system excluding the S-basis. Thus for an $H$ and a $Q_{x}$ in an arbitrary S-system including the S-basis, equation (6.70) should be read as:

$$
\begin{array}{r}
\frac{1}{2} \operatorname{tr}\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} H_{\alpha} V_{0}\left(S^{*} V_{0}\right)^{-1} \cdot S^{*} A^{*} Q_{y}^{-1} A S \cdot\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} H_{\beta} V_{0}\left(S^{*} V_{0}\right)^{-1} \cdot S^{*} A^{*} Q_{y}^{-1} A S\right] \hat{\theta}^{\beta} \\
=\frac{1}{2} \operatorname{tr}\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} H_{\alpha} V_{0}\left(S^{*} V_{0}\right)^{-1} \cdot S^{*} A^{*} Q_{y}^{-1} A S . \Delta \underline{x} \Delta \underline{x}^{*} \cdot S^{*} A^{*} Q_{y}^{-1} A S\right] \tag{6.71}
\end{array}
$$

In this equation matrix $S^{*} A^{*} Q_{y}^{-1} A S$ plays the role of weight matrix. Thus $\left(S^{*} A^{*} Q_{y}^{-1} A S\right)^{-1}$ plays the role of variance matrix. We will now investigate the consequences if one replaces or approximates $\left(S^{*} A^{*} Q_{y}^{-1} A S\right)^{-1}$ by

$$
\begin{equation*}
\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} \sigma^{2} I V_{0}\left(S^{*} V_{0}\right)^{-1}\right] \tag{6.72}
\end{equation*}
$$

If we replace $S^{*} A^{*} Q_{y}^{-1} A S$ in (6.71) by the inverse of (6.72) we get:

$$
\begin{array}{r}
\frac{1}{2} \operatorname{tr}\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} H_{\alpha} V_{0}\left(S^{*} V_{0}\right)^{-1} \cdot\left(S^{*} V_{0}\right)\left(\sigma^{2} V_{0}^{*} V_{0}\right)^{-1}\left(V_{0}^{*} S\right) \ldots\right. \\
\left.\ldots\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} H_{\beta} V_{0}\left(S^{*} V_{0}\right)^{-1} \cdot\left(S^{*} V_{0}\right)\left(\sigma^{2} V_{0}^{*} V_{0}\right)^{-1}\left(V_{0}^{*} S\right)\right] \hat{\theta}^{\beta}= \\
\frac{1}{2} \operatorname{tr}\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} H_{\alpha} V_{0}\left(S^{*} V_{0}\right)^{-1} \cdot\left(S^{*} V_{0}\right)\left(\sigma^{2} V_{0}^{*} V_{0}\right)^{-1}\left(V_{0}^{*} S\right) \cdot \Delta \underline{x} \Delta \underline{x}^{*} \cdot\left(S^{*} V_{0}\right)\left(\sigma^{2} V_{0}^{*} V_{0}\right)^{-1}\left(V_{0}^{*} S\right)\right] \tag{6.73}
\end{array}
$$

or

$$
\begin{gather*}
\frac{1}{2} \sigma^{-4} \operatorname{tr}\left[V_{0}^{*} H_{\alpha} V_{0}\left(V_{0}^{*} V_{0}\right)^{-1} V_{0}^{*} H_{\beta} V_{0}\left(V_{0}^{*} V_{0}\right)^{-1}\right] \underline{\theta}^{\beta}= \\
\frac{1}{2} \sigma^{-4} \operatorname{tr}\left[V_{0}^{*} H_{\alpha} V_{0}\left(V_{0}^{*} V_{0}\right)^{-1} V_{0}^{*} S . \Delta \underline{x} \Delta \underline{x}^{*} S^{*} V_{0}\left(V_{0}^{*} V_{0}\right)^{-1}\right] \tag{6.74}
\end{gather*}
$$

Note that the projector

$$
\begin{equation*}
P_{R\left(A^{*}\right), N(A)}=V_{0}\left(V_{0}^{*} V_{0}\right)^{-1} V_{0}^{*}=I-V_{1}\left(V_{1}^{*} V_{1}\right)^{-1} V_{1}^{*} \tag{6.75}
\end{equation*}
$$

is the S-transformation that corresponds with the minimum-norm solution. With (6.75), equation (6.74) may be written as

$$
\begin{equation*}
\operatorname{tr}\left[H_{\alpha} P H_{\beta} P\right] \underline{\hat{\theta}}^{\beta}=\operatorname{tr}\left[H_{\alpha} P S . \Delta \underline{x} \Delta \underline{x}^{*} S^{*} P\right] \tag{6.76}
\end{equation*}
$$

If we replace $\Delta \underline{x} \Delta \underline{x}^{*}$ by its expectation $\left(S^{*} A^{*} Q_{y}^{-1} A S\right)^{-1}$, we get

$$
\begin{equation*}
\operatorname{tr}\left[H_{\alpha} P H_{\beta} P\right] \hat{\hat{\theta}}^{\beta}=\operatorname{tr}\left[H_{\alpha} P S\left(S^{*} A^{*} Q_{y}^{-1} A S\right)^{-1} S^{*} P\right] \tag{6.77}
\end{equation*}
$$

or with $Q_{x}=S\left(S^{*} A^{*} Q_{y}^{-1} A S\right)^{-1} S^{*}$,

$$
\begin{equation*}
\operatorname{tr}\left[H_{\alpha} P H_{\beta} P\right] \underline{\hat{\theta}}^{\beta}=\operatorname{tr}\left[H_{\alpha} P Q_{x} P\right] \tag{6.78}
\end{equation*}
$$

This shows that:

1. The solution is independent of the chosen S-system, because of the occurrence of $P$ in (6.78),
2. The solution corresponds to the case that $H$ and $Q_{x}$ are defined in the minimum-norm Ssystem.

Remark: Because of the structure of the normal matrix in (6.78), it will be possible for some cases to solve (6.78) analytically. For example consider a leveling network of $n$ points with the simplest substitute matrix $H$. Then

$$
\begin{equation*}
H=\Delta d^{2} I_{n}, \quad \text { and } P=I_{n}-e\left(e^{*} e\right)^{-1} e^{*} \tag{6.79}
\end{equation*}
$$

with

$$
\begin{equation*}
e=(1,1, \ldots, 1)^{*} \tag{6.80}
\end{equation*}
$$

Substitution of (6.79) into (6.78) gives

$$
\begin{equation*}
\operatorname{tr}[P] \Delta \hat{d}^{2}=\operatorname{tr}\left[P Q_{x} P\right] \tag{6.81}
\end{equation*}
$$

or

$$
\begin{align*}
& \Delta \hat{d}^{2}=\frac{\operatorname{tr}\left[P Q_{x} P\right]}{n-1}  \tag{6.82}\\
& \sigma_{\Delta \hat{d}^{2}}^{2}=\frac{2 \sigma^{4}}{n-1}
\end{align*}
$$

Note 1: Here we have a link with the minimum trace.
Note 2: This $\Delta \hat{d}^{2}$ is related to Helmert's mittler punktfehler.
We will now derive the with (6.78) corresponding teststatistic $T_{m-n}$. We have

$$
\begin{array}{r}
T(\hat{\theta})=\left[\operatorname{vec}\left(\left(V_{0}^{*} S\right)^{-1} V_{0}^{*}\left(Q_{x}-\hat{H}\right) V_{0}\left(S^{*} V_{0}\right)^{-1}\right)\right]^{*}\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} \sigma^{2} I V_{0}\left(S^{*} V_{0}\right)^{-1}\right]^{-1} \otimes \\
\ldots\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} \sigma^{2} I V_{0}\left(S^{*} V_{0}\right)^{-1}\right]^{-1}\left[\operatorname{vec}\left(\left(V_{0}^{*} S\right)^{-1} V_{0}^{*}\left(Q_{x}-\hat{H}\right) V_{0}\left(S^{*} V_{0}\right)^{-1}\right]\right. \tag{6.83}
\end{array}
$$

or

$$
\begin{align*}
& T(\hat{\theta})=\operatorname{tr}\{ {\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} \sigma^{2} I V_{0}\left(S^{*} V_{0}\right)^{-1}\right]^{-1}\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*}\left(Q_{x}-\hat{H}\right) V_{0}\left(S^{*} V_{0}\right)^{-1}\right] } \\
&\left.\ldots\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} \sigma^{2} V_{0}\left(S^{*} V_{0}\right)^{-1}\right]^{-1}\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*}\left(Q_{x}-\hat{H}\right) V_{0}\left(S^{*} V_{0}\right)^{-1}\right]\right\} \tag{6.84}
\end{align*}
$$

or

$$
\begin{equation*}
T(\hat{\theta})=\sigma^{-4} \operatorname{tr}\left[P\left(Q_{x}-\hat{H}\right) P\left(Q_{x}-\hat{H}\right)\right] \tag{6.85}
\end{equation*}
$$

We may write (6.85) also as

$$
\begin{align*}
T(\hat{\theta}) & =\sigma^{-4}\left\{\operatorname{tr}\left[P Q_{x} P Q_{x}\right]-\operatorname{tr}\left[P Q_{x} P \hat{H}\right]-\operatorname{tr}\left[P \hat{H} P Q_{x}\right]+\operatorname{tr}[P \hat{H} P \hat{H}]\right\} \\
& =\sigma^{-4}\left\{\operatorname{tr}\left[P Q_{x} P Q_{x}\right]-2 \operatorname{tr}\left[P Q_{x} P \hat{H}\right]+\operatorname{tr}[P \hat{H} P \hat{H}]\right\} \tag{6.86}
\end{align*}
$$

And with (6.78), this simplifies to

$$
\begin{equation*}
T(\hat{\theta})=\sigma^{-4} \operatorname{tr}\left[P Q_{x}\left(P Q_{x}-P \hat{H}\right)\right] \tag{6.87}
\end{equation*}
$$

We will now derive with (6.78) the corresponding teststatistic $\underline{w}$ : Let us assume that we want to test how well the variance $a^{*} Q_{x} a$ of an estimable function $a^{*} x$ fits the model value $a^{*} \hat{H} a$. Then, the following two hypotheses should be considered:

$$
\begin{cases}H_{0}: & E\left\{\operatorname{vec}\left(\Delta \underline{x} \Delta \underline{x}^{*}\right)\right\}=\operatorname{vec}\left(H_{\alpha}\right) \theta^{\alpha}  \tag{6.88}\\ H_{A}: & E\left\{\operatorname{vec}\left(\Delta \underline{x} \Delta \underline{x}^{*}\right)\right\}=\operatorname{vec}\left(H_{\alpha}\right) \theta^{\alpha}+\operatorname{vec}\left(a a^{*}\right)\end{cases}
$$

These hypotheses should actually be read as:

$$
\left\{\begin{align*}
H_{0}: \quad E\left\{\operatorname{vec}\left[S^{*} A^{*} Q_{y}^{-1} A S\right]\right\} & =\operatorname{vec}\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} H_{\alpha} V_{0}\left(S^{*} V_{0}\right)^{-1}\right] \theta^{\alpha}  \tag{6.89}\\
H_{A}: E\left\{\operatorname{vec}\left[S^{*} A^{*} Q_{y}^{-1} A S\right]\right\} & =\operatorname{vec}\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} H_{\alpha} V_{0}\left(S^{*} V_{0}\right)^{-1}\right] \theta^{\alpha} \\
& +\operatorname{vec}\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} a a^{*} V_{0}\left(S^{*} V_{0}\right)^{-1}\right]
\end{align*}\right.
$$

As covariance matrix, we take

$$
\begin{equation*}
\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} \sigma^{2} I V_{0}\left(S^{*} V_{0}\right)^{-1}\right] \otimes\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} \sigma^{2} I V_{0}\left(S^{*} V_{0}\right)^{-1}\right] \tag{6.90}
\end{equation*}
$$

with (6.89) and (6.90), it follows that:

$$
\begin{array}{r}
c_{y}^{*} Q_{y}^{-1} Q_{e} Q_{y}^{-1} c_{y}=\operatorname{vec}\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} a a^{*} V_{0}\left(S^{*} V_{0}\right)^{-1}\right]^{*}\left[\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} \sigma^{2} V_{0}\left(S^{*} V_{0}\right)^{-1}\right]^{-1} \otimes\right. \\
\left.\left[V_{0}^{*} S\right)^{-1} V_{0}^{*} \sigma^{2} V_{0}\left(S^{*} V_{0}\right)^{-1}\right]^{-1}-\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} \sigma^{2} V_{0}\left(S^{*} V_{0}\right)^{-1}\right]^{-1} \otimes\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} \sigma^{2} V_{0}\left(S^{*} V_{0}\right)^{-1}\right]^{-1} \\
\boldsymbol{e c}\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} H_{\alpha} V_{0}\left(S^{*} V_{0}\right)^{-1}\right]\left[\operatorname{tr}\left(H_{\alpha} P H_{\beta} P\right)\right]^{-1} \operatorname{vec}\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} H_{\beta} V_{0}\left(S^{*} V_{0}\right)^{-1}\right]^{*} \\
\left.\left.\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} \sigma^{2} V_{0}\left(S^{*} V_{0}\right)^{-1}\right]^{-1} \otimes\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} \sigma^{2} V_{0}\left(S^{*} V_{0}\right)^{-1}\right]^{-1}\right] \operatorname{vec}\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} a a^{*} V_{0}\left(S^{*} V_{0}\right)^{-1}\right]
\end{array}
$$

or

$$
\begin{array}{r}
c_{y}^{*} Q_{y}^{-1} Q_{\hat{e}} Q_{y}^{-1} c_{y}=\frac{1}{2} \operatorname{tr}\left\{\left(S^{*} V_{0} \sigma^{-2}\left(V_{0}^{*} V_{0}\right)^{-1} V_{0}^{*} S\right)\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} a a^{*} V_{0}\left(S^{*} V_{0}\right)^{-1} \ldots\right. \\
\left.\left.\left(S^{*} V_{0}\right) \sigma^{-2}\left(V_{0}^{*} V_{0}\right)^{-1} V_{0}^{*} S\right)\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} a a^{*} V_{0}\left(S^{*} V_{0}\right)^{-1}\right\} \\
-\frac{1}{2} \operatorname{tr}\left\{\left(S^{*} V_{0}\right) \sigma^{-2}\left(V_{0}^{*} V_{0}\right)^{-1} V_{0}^{*} S .\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} H_{\alpha} V_{0}\left(S^{*} V_{0}\right)^{-1} \ldots\right. \\
\left.\left(S^{*} V_{0}\right) \sigma^{-2}\left(V_{0}^{*} V_{0}\right)^{-1} V_{0}^{*} S .\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} a a^{*} V_{0}\left(S^{*} V_{0}\right)^{-1}\right\} 2 \sigma^{4}\left[\operatorname{tr}\left(H_{\alpha} P H_{\beta} P\right)\right]^{-1} \ldots \\
\frac{1}{2} \operatorname{tr}\left\{\left(S^{*} V_{0}\right) \sigma^{-2}\left(V_{0}^{*} V_{0}\right)^{-1} V_{0}^{*} S .\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} a a^{*} V_{0}\left(S^{*} V_{0}\right)^{-1} \ldots\right. \\
\left.\left(S^{*} V_{0}\right) \sigma^{-2}\left(V_{0}^{*} V_{0}\right)^{-1} V_{0}^{*} S .\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} H_{\beta} V_{0}\left(S^{*} V_{0}\right)^{-1}\right\} \tag{6.91}
\end{array}
$$

or

$$
\begin{align*}
c_{y}^{*} Q_{y}^{-1} Q_{\hat{e}} Q_{y}^{-1} c_{y} & =\frac{1}{2} \sigma^{-4}\left(a^{*} P a\right)^{2}-\frac{1}{2} \sigma^{-4}\left(a^{*} P H_{\alpha} P a\right) 2 \sigma^{4}\left(\operatorname{tr}\left[H_{\alpha} P H_{\beta} P\right]\right)^{-1} \frac{1}{2} \sigma^{-4}\left(a^{*} P H_{\beta} P a\right) \\
& =\frac{1}{2} \sigma^{-4}\left\{\left(a^{*} a\right)^{2}-\left(a^{*} H_{\alpha} a\right)\left(\operatorname{tr}\left[H_{\alpha} P H_{\beta} P\right]\right)^{-1}\left(a^{*} H_{\beta} a\right)\right\} \tag{6.92}
\end{align*}
$$

since $a$ is an estimable function, i.e., $P a=a$.

$$
\begin{align*}
c_{y}^{*} Q_{y}^{-1} \hat{e}= & \frac{1}{2} \operatorname{vec}\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} a a^{*} V_{0}\left(S^{*} V_{0}\right)^{-1}\right]^{*}\left[\left(S^{*} V_{0}\right) \sigma^{-2}\left(V_{0}^{*} V_{0}\right)^{-1}\left(V_{0}^{*} S\right)\right] \otimes \\
& {\left.\left[S^{*} V_{0}\right) \sigma^{-2}\left(V_{0}^{*} V_{0}\right)^{-1}\left(V_{0}^{*} S\right)\right]\left[\operatorname{vec}\left[\left(V_{0}^{*} S\right)^{-1} V_{0}^{*}\left(Q_{x}-\hat{H}\right) V_{0}\left(S^{*} V_{0}\right)^{-1}\right]\right] } \tag{6.93}
\end{align*}
$$

or

$$
\begin{array}{r}
c_{y}^{*} Q_{y}^{-1} \hat{e}=\frac{1}{2} \operatorname{tr}\left[\left(S^{*} V_{0}\right)\left(V_{0}^{*} V_{0}\right)^{-1}\left(V_{0}^{*} S\right) \cdot\left(V_{0}^{*} S\right)^{-1} V_{0}^{*}\left(Q_{x}-\hat{H}\right) V_{0}\left(S^{*} V_{0}\right)^{-1}\right. \\
\left.\left.S^{*} V_{0}\right)\left(V_{0}^{*} V_{0}\right)^{-1}\left(V_{0}^{*} S\right) \cdot\left(V_{0}^{*} S\right)^{-1} V_{0}^{*} a a^{*} V_{0}\left(S^{*} V_{0}\right)^{-1}\right] \sigma^{-4} \tag{6.94}
\end{array}
$$

or

$$
\begin{equation*}
c_{y}^{*} Q_{y}^{-1} \hat{e}=\frac{1}{2} \sigma^{-4} a^{*} P\left(Q_{x}-\hat{H}\right) P a=\frac{1}{2} \sigma^{-4} a^{*}\left(Q_{x}-\hat{H}\right) a \tag{6.95}
\end{equation*}
$$

From (6.92) and (6.95) follows that:

$$
\begin{equation*}
w=\frac{1}{\sqrt{2} \sigma^{2}} \cdot \frac{a^{*}\left(Q_{x}-\hat{H}\right) a}{\left[\left(a^{*} a\right)^{2}-\left(a^{*} H_{\alpha} a\right)\left(\operatorname{tr}\left[H_{\alpha} P H_{\beta} P\right]\right)^{-1}\left(a^{*} H_{\beta} a\right)\right]^{1 / 2}} \tag{6.96}
\end{equation*}
$$

Example: If $H=\Delta d^{2} I_{n}$ and $P=I_{n}-e\left(e^{*} e\right) e^{*}$, then

$$
\begin{equation*}
w=\frac{1}{\sqrt{2} \sigma^{2}} \cdot \frac{a^{*}\left(Q_{x}-\hat{H}\right) a}{a^{*} a} \cdot\left(\frac{n-1}{n-2}\right)^{1 / 2} \tag{6.97}
\end{equation*}
$$

Note that $w_{\max }$ in this case is related to the generalized eigenvalue problem $\left|Q_{x}-\lambda \hat{H}\right|=0$. Hence, we have established a like with the ordinary procedure of the generalized eigenvalue problem

$$
\begin{equation*}
w_{\max }=\frac{1}{\sqrt{2} \sigma^{2}} \cdot\left(\frac{n-1}{n-2}\right)^{1 / 2}\left(\lambda_{\max }-1\right) \Delta \hat{d}^{2} \tag{6.98}
\end{equation*}
$$

## Appendix A

## Backgrounds

## A. 1 The Moments of $\underline{t} \sim N\left(0, Q_{t}\right)$

The moment generating function of $\underline{t}$ is defined as

$$
\begin{equation*}
\Phi(s)=E\left\{\exp \left[s^{*} \underline{t}\right]\right\}=\int p_{\underline{\underline{t}}}(t) \exp \left[s^{*} t\right] d t \tag{A.1}
\end{equation*}
$$

with

$$
\begin{equation*}
p_{\underline{t}}(t)=(2 \pi)^{-1 / 2}\left|Q_{t}\right|^{-1 / 2} \exp \left[-\frac{1}{2} t^{*} Q_{t}^{-1} t\right] \tag{A.2}
\end{equation*}
$$

Substitution of (A.2) into (A.1) gives

$$
\begin{equation*}
\Phi(s)=\int(2 \pi)^{-1 / 2}\left|Q_{t}\right|^{-1 / 2} \exp \left[-\frac{1}{2}\left\{t^{*} Q_{t}^{-1} t-2 s^{*} t\right\}\right] d t \tag{A.3}
\end{equation*}
$$

Substitution of

$$
\begin{equation*}
\exp \left[-\frac{1}{2}\left\{t^{*} Q_{t}^{-1} t-2 s^{*} t\right\}\right]=\exp \left[-\frac{1}{2}\left(t-Q_{t} s\right)^{*} Q_{t}^{-1}\left(t-Q_{t} s\right)\right] \exp \left[-\frac{1}{2} s^{*} Q_{t} s\right] \tag{A.4}
\end{equation*}
$$

into (A.3) gives

$$
\begin{equation*}
\Phi(s)=\exp \left[\frac{1}{2} s^{*} Q_{t} s\right] \tag{A.5}
\end{equation*}
$$

From (A.1) follows that:

$$
\begin{equation*}
\partial_{i_{1}, \ldots, i_{\alpha}}^{\alpha} \Phi(s)=\int p_{\underline{t}}(t) \partial_{i_{1}, \ldots, i_{\alpha}}^{\alpha}\left[\exp \left(s^{*} t\right)\right] d t, \quad i_{1}, \ldots, i_{\alpha}=1,2, \ldots, b \tag{A.6}
\end{equation*}
$$

Substitution of

$$
\begin{equation*}
\partial_{i_{1}, \ldots, i_{\alpha}}^{\alpha}\left[\exp \left(s^{*} t\right)\right]=t_{i_{1}} t_{i_{2}} \ldots t_{i_{\alpha}} \exp \left(s^{*} t\right) \tag{A.7}
\end{equation*}
$$

into (A.6) gives:

$$
\begin{equation*}
\partial_{i_{1}, \ldots, i_{\alpha}}^{\alpha} \Phi(s)=\int p_{\underline{t}}(t) t_{i_{1}} t_{i_{2}} \ldots t_{i_{\alpha}} \exp \left(s^{*} t\right) d t \tag{A.8}
\end{equation*}
$$

Evaluation at $s=0$, shows that

$$
\begin{equation*}
\left.\partial_{i_{1}, \ldots, i_{\alpha}}^{\alpha} \Phi(s)\right|_{s=0}=E\left\{\underline{t}_{i_{1}} \underline{t}_{i_{2}} \cdots \underline{t}_{i_{\alpha}}\right\} \tag{A.9}
\end{equation*}
$$

If we write (A.5) in index notation like

$$
\begin{equation*}
\Phi(s)=\exp \left[\frac{1}{2} q^{i j} s_{i} s_{j}\right], \quad i, j=1,2, \ldots, b \tag{A.10}
\end{equation*}
$$

it follows that

$$
\begin{align*}
&\left.\partial_{i} \Phi(s)\right|_{s=0}=0,\left.\quad \partial_{i j}^{2} \Phi(s)\right|_{s=0} \\
&=q^{i j}  \tag{A.11}\\
&\left.\partial_{i j k}^{3} \Phi(s)\right|_{s=0}=0,\left.\quad \partial_{i j k l}^{4} \Phi(s)\right|_{s=0}
\end{align*}=q^{i j} q^{k l}+q^{i k} q^{j l}+q^{i l} q^{j k}, ~ l
$$

This, together with (A.9) shows that

$$
\begin{align*}
E\left\{\underline{t}_{i}\right\} & =0, \quad E\left\{\underline{t}_{i} \underline{t}_{j}\right\}  \tag{A.12}\\
E\left\{\underline{t}_{i} \underline{t}_{j} \underline{t}_{k}\right\} & =0, \quad E\left\{\underline{t}_{i} \underline{t}_{j} \underline{t}_{k} \underline{t}_{l}\right\}
\end{align*}=q^{i j} q^{k l}+q^{i k} q^{j l}+q^{i l} q^{j k},
$$

## A. 2 The Variance Matrix of $\operatorname{vec}\left(\underline{t t}^{*}\right)$, with $\underline{t} \sim N\left(0, Q_{t}\right)$

First some standard results on the vec-operator and the Kronecker product. Consider a matrix $A=\left[a_{i j}\right]$ of order $m \times n$ and a matrix $B=\left[b_{i j}\right]$ of order $r \times s$. The Kronecker product of the two matrices, denoted by $A \otimes B$ is defined as the partitioned matrix

$$
A \otimes B=\left[\begin{array}{cccc}
a_{11} B & a_{12} B & \cdots & a_{1 n} B  \tag{A.13}\\
a_{21} B & a_{22} B & \cdots & a_{2 n} B \\
\vdots & \vdots & \ddots & \vdots \\
a_{m 1} B & a_{m 2} B & \cdots & a_{m n} B
\end{array}\right]
$$

$A \otimes B$ is seen to be a matrix of order $m r \times n s$. It has $m n$ blocks, the $i j^{t h}$ block is the matrix $a_{i j} B$ of the order $r \times s$. The following properties hold for the Kronecker product:

$$
\begin{align*}
\operatorname{vec}(A B C) & =\left(C^{*} \otimes A\right) \operatorname{vec}(B) \\
\operatorname{vec}(A)^{*} \operatorname{vec}(B) & =\operatorname{trace}\left(A^{*} B\right) \\
\operatorname{trace}(A B C D) & =\operatorname{vec}\left(D^{*}\right)^{*}\left(C^{*} \otimes A\right) \operatorname{vec}(B) \\
& =\operatorname{vec}(D)^{*}\left(A \otimes C^{*}\right) \operatorname{vec}\left(B^{*}\right) \\
\operatorname{vec}\left(a b^{*}\right) & =b \otimes a \\
(A \otimes B)^{*} & =A^{*} \otimes B^{*} \\
\operatorname{rank}(A \otimes B) & =\operatorname{rank}(A) \operatorname{rank}(B) \\
(A \otimes B)^{-1} & =A^{-1} \otimes B^{-1} \\
\operatorname{trace}(A \otimes B) & =\operatorname{trace}(A) \operatorname{trace}(B) \\
\left(A_{1}+A_{2}\right) \otimes B & =A_{1} \otimes B+A_{2} \otimes B \\
A \otimes\left(B_{1}+B_{2}\right) & =A \otimes B_{1}+A \otimes B_{2} \\
\left(A_{1} A_{2}\right) \otimes\left(B_{1} B_{2}\right) & =\left(A_{1} \otimes B_{1}\right)\left(A_{2} \otimes B_{2}\right) \tag{A.14}
\end{align*}
$$

The variance matrix of $\operatorname{vec}\left(\underline{t t}^{*}\right)$ consists of terms like

$$
\begin{equation*}
E\left\{\left[\underline{t}_{i} \underline{t}_{j}-E\left\{\underline{t}_{i} \underline{t}_{j}\right\}\right]\left[\underline{t}_{k} \underline{t}_{l}-E\left\{\underline{t}_{k} \underline{t}_{l}\right\}\right]\right\} \quad i, j, k, l=1,2, \ldots, b \tag{A.15}
\end{equation*}
$$

Since

$$
\begin{equation*}
E\left\{\left[\underline{t}_{i} \underline{t}_{j}-E\left\{\underline{t}_{i} \underline{t}_{j}\right\}\right]\left[\underline{t}_{k} \underline{t}_{l}-E\left\{\underline{t}_{k} \underline{t}_{l}\right\}\right]\right\}=E\left\{\underline{t}_{i} \underline{t}_{j} \underline{t}_{k} \underline{t}_{l}\right\}-E\left\{\underline{t}_{i} \underline{t}_{j}\right\} E\left\{\underline{t}_{k} \underline{t}_{l}\right\} \tag{A.16}
\end{equation*}
$$

substitution of (A.12) gives

$$
\begin{equation*}
E\left\{\left[\underline{t}_{i} \underline{t}_{j}-E\left\{\underline{t}_{i} \underline{t}_{j}\right\}\right]\left[\underline{t}_{k} \underline{t}_{l}-E\left\{\underline{t}_{k} \underline{t}_{l}\right\}\right]\right\}=q^{i k} q^{j l}+q^{i l} q^{j k} \tag{A.17}
\end{equation*}
$$

From (A.17) follows that

$$
\begin{equation*}
E\left\{\left[\underline{t}_{i} \underline{t}-E\left\{\underline{t}_{i} \underline{t}\right\}\right]\left[\underline{t}_{k} \underline{t}-E\left\{\underline{t}_{k} \underline{t}\right\}\right]^{*}\right\}=e_{i}^{*} Q_{t} e_{k} Q_{t}+Q_{t} e_{k} e_{i}^{*} Q_{t} \tag{A.18}
\end{equation*}
$$

with

$$
\begin{equation*}
e_{i}=(0, \ldots, 0,1,0, \ldots, 0)^{*} \tag{A.19}
\end{equation*}
$$

From (A.18) follows that

$$
\begin{equation*}
Q_{v e c\left(\underline{t t^{*}}\right)}=\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{i}^{*} Q_{t} e_{k} Q_{t}+\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes Q_{t} e_{k} e_{i}^{*} Q_{t} \tag{A.20}
\end{equation*}
$$

Since

$$
\begin{equation*}
\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{i}^{*} Q_{t} e_{k} Q_{t}=\sum_{i} \sum_{k}\left(e_{i}^{*} Q_{t} e_{k}\right) e_{i} e_{k}^{*} \otimes Q_{t} \tag{A.21}
\end{equation*}
$$

and

$$
\begin{equation*}
Q_{t}=\sum_{i} \sum_{k}\left(e_{i}^{*} Q_{t} e_{k}\right) e_{i} e_{k}^{*} \tag{A.22}
\end{equation*}
$$

it follows that

$$
\begin{equation*}
\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{i}^{*} Q_{t} e_{k} Q_{t}=Q_{t} \otimes Q_{t} \tag{A.23}
\end{equation*}
$$

With (A.18), it follows that

$$
\begin{aligned}
\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes Q_{t} e_{k} e_{i}^{*} Q_{t} & =\sum_{i} \sum_{k} e_{i} e_{k}^{*} I \otimes Q_{t} e_{k} e_{i}^{*} Q_{t} \\
& =\sum_{i} \sum_{k}\left(e_{i} e_{k}^{*} \otimes Q_{t}\right)\left(I \otimes e_{k} e_{i}^{*} Q_{t}\right) \\
& =\sum_{i} \sum_{k}\left(I e_{i} e_{k}^{*} \otimes Q_{t} I\right)\left(I I \otimes e_{k} e_{i}^{*} Q_{t}\right) \\
& =\sum_{i} \sum_{k}\left(I \otimes Q_{t}\right)\left(e_{i} e_{k}^{*} \otimes I\right)\left(I \otimes e_{k} e_{i}^{*}\right)\left(I \otimes Q_{t}\right)
\end{aligned}
$$

or

$$
\begin{equation*}
\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes Q_{t} e_{k} e_{i}^{*} Q_{t}=\left(I \otimes Q_{t}\right)\left(\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right)\left(I \otimes Q_{t}\right) \tag{A.24}
\end{equation*}
$$

Matrix $\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}$ has the following properties:
1.

$$
\begin{equation*}
\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}=\text { symmetric } \tag{A.25}
\end{equation*}
$$

2. 

$$
\begin{equation*}
\left(\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right)\left(\sum_{j} \sum_{l} e_{j} e_{l}^{*} \otimes e_{l} e_{j}^{*}\right)=I \tag{A.26}
\end{equation*}
$$

3. 

$$
\begin{equation*}
\left(\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right)(a \otimes b)=b \otimes a \tag{A.27}
\end{equation*}
$$

4. 

$$
\begin{equation*}
\left(\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right)(A \otimes B)=(B \otimes A)\left(\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right. \tag{A.28}
\end{equation*}
$$

Proof of (1): Trivial
Proof of (2):

$$
\begin{align*}
\left(\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right)\left(\sum_{j} \sum_{l} e_{j} e_{l}^{*} \otimes e_{l} e_{j}^{*}\right) & =\sum_{i} \sum_{k} \sum_{j} \sum_{l}\left(e_{i} e_{k}^{*} e_{j} e_{l}^{*} \otimes e_{k} e_{i}^{*} e_{l} e_{j}^{*}\right) \\
& =\sum_{i} \sum_{k} \sum_{j} \sum_{l}\left(\delta_{k j} \delta_{i l} e_{i} e_{l}^{*} \otimes e_{k} e_{j}^{*}\right) \\
& =\sum_{i} \sum_{k} e_{i} e_{i}^{*} \otimes e_{k} e_{k}^{*} \\
& =\left(\sum_{i} e_{i} e_{i}^{*} \otimes \sum_{k} e_{k} e_{k}^{*}\right) \\
& =I \otimes I=I \tag{A.29}
\end{align*}
$$

Proof of (3):

$$
\begin{align*}
\left(\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right)(a \otimes b) & =\sum_{i} \sum_{k} e_{i} e_{k}^{*} a \otimes e_{k} e_{i}^{*} b \\
& =\sum_{i} \sum_{k} a_{k} e_{i} \otimes b_{i} e_{k} \\
& =\left(\sum_{i} b_{i} e_{i}\right) \otimes\left(\sum_{k} a_{k} e_{k}\right)=b \otimes a \tag{A.30}
\end{align*}
$$

Proof of (4): $\quad A=\sum_{\alpha} a_{\alpha} e_{\alpha}^{*} ; B=\sum_{\beta} b_{\beta} e_{\beta}^{*} ;$

$$
\begin{align*}
\left(\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right)(A \otimes B) & =\left(\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right)\left(\sum_{\alpha} \sum_{\beta} a_{\alpha} e_{\alpha}^{*} \otimes b_{\beta} e_{\beta}^{*}\right) \\
& =\left(\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right)\left(\sum_{\alpha} \sum_{\beta}\left(a_{\alpha} \otimes b_{\beta}\right)\left(e_{\alpha}^{*} \otimes e_{\beta}^{*}\right)\right) \\
& =\sum_{\alpha} \sum_{\beta} b_{\beta} \otimes a_{\alpha}\left(e_{\alpha}^{*} \otimes e_{\beta}^{*}\right) \\
& =\sum_{\alpha} \sum_{\beta} b_{\beta} \otimes a_{\alpha}\left[\left(\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right)\left(e_{\beta} \otimes e_{\alpha}\right)\right]^{*} \\
& =\sum_{\alpha} \sum_{\beta}\left(b_{\beta} \otimes a_{\alpha}\right)\left(e_{\beta}^{*} \otimes e_{\alpha}^{*}\right) \sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*} \\
& =\sum_{\alpha} \sum_{\beta}\left(b_{\beta} e_{\beta}^{*} \otimes a_{\alpha} e_{\alpha}^{*}\right)\left(\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right) \\
& =(B \otimes A)\left(\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right) \tag{A.31}
\end{align*}
$$

Using (A.28) we may write (A.24) as

$$
\begin{equation*}
\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes Q_{t} e_{k} e_{i}^{*} Q_{t}=\left(\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right)\left(Q_{t} \otimes Q_{t}\right) \tag{A.32}
\end{equation*}
$$

Substitution of (A.23) and (A.32) into (A.20) finally gives

$$
\begin{align*}
Q_{v e c\left(\underline{t \underline{t}^{*}}\right)} & =\left[I+\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right]\left[Q_{t} \otimes Q_{t}\right] \\
& =\left[Q_{t} \otimes Q_{t}\right]\left[I+\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right]  \tag{A.33}\\
& =\frac{1}{2}\left[I+\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right]\left[Q_{t} \otimes Q_{t}\right]\left[I+\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right]
\end{align*}
$$

## A. 3 The Singularity of $Q_{\text {vec }}$

It will be clear that the matrix $Q_{v e c}$ has to be singular. Since $Q_{t} \otimes Q_{t}$ is regular, the matrix

$$
\begin{equation*}
\left[I+\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right] \tag{A.34}
\end{equation*}
$$

has to be singular. Since (see also (A.25, A.26, A. 27 and A.28))

$$
\begin{equation*}
\left[I+\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right]\left[I+\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right]=2\left[I+\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right] \tag{A.35}
\end{equation*}
$$

it follows that the matrix

$$
\begin{equation*}
P_{b^{2} \times b^{2}}=\frac{1}{2}\left[I+\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right] \tag{A.36}
\end{equation*}
$$

is a projector (idempotent). We will know derive some properties of the projector $P$. Since the rank of a projector equals its trace, we have:

$$
\begin{align*}
\operatorname{rank}(P) & =\frac{1}{2} \operatorname{trace}\left[I_{b^{2}}+\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right] \\
& =\frac{1}{2} b^{2}+\frac{1}{2} \operatorname{trace}\left[\sum_{i} \sum_{k} e_{i} e_{k}^{*} \otimes e_{k} e_{i}^{*}\right] \\
& =\frac{1}{2} b^{2}+\frac{1}{2} \sum_{i} \sum_{k} \operatorname{trace}\left[e_{i} e_{k}^{*}\right] \operatorname{trace}\left[e_{k} e_{i}^{*}\right]  \tag{A.37}\\
& =\frac{1}{2} b^{2}+\frac{1}{2} \sum_{i} \sum_{k}\left(\operatorname{trace}\left[e_{i} e_{k}^{*}\right]\right)^{2}
\end{align*}
$$

or

$$
\begin{equation*}
\operatorname{rank}(P)=\frac{1}{2} b(b+1) \tag{A.38}
\end{equation*}
$$

From this follows that the dimension of the range space and null space of $P$ are

$$
\begin{align*}
\operatorname{dim} R(P) & =\frac{1}{2} b(b+1)  \tag{A.39}\\
\operatorname{dim} N(P) & =b^{2}-\frac{1}{2} b(b+1)=\frac{1}{2} b(b-1)
\end{align*}
$$

Since

$$
\begin{equation*}
P(a \otimes b)=\frac{1}{2}(a \otimes b+b \otimes a) \tag{A.40}
\end{equation*}
$$

and

$$
\begin{equation*}
a \otimes b=\operatorname{vec}\left(b a^{*}\right) \tag{A.41}
\end{equation*}
$$

it follows that

$$
\begin{equation*}
\operatorname{Pvec}\left(b a^{*}\right)=\frac{1}{2} \operatorname{vec}\left(b a^{*}+a b^{*}\right) \tag{A.42}
\end{equation*}
$$

Let $X$ be an arbitrary matrix of order $b^{2} \times b^{2}$ with column vectors $x_{i}, i=1,2, \ldots, b^{2}$. Then $X=\sum_{i} x_{i} e_{i}^{*}$ and thus $\operatorname{vec}(X)=\sum_{i} \operatorname{vec}\left(x_{i} e_{i}^{*}\right)=\sum_{i} e_{i} \otimes x_{i}$. This shows with (A.42) that

$$
\begin{equation*}
\operatorname{Pvec}(X)=\frac{1}{2} \sum_{i} \operatorname{vec}\left(x_{i} e_{i}^{*}+e_{i} x_{i}^{*}\right)=\frac{1}{2} \operatorname{vec}\left[\sum_{i} x_{i} e_{i}^{*}+\left(\sum_{i} x_{i} e_{i}^{*}\right)^{*}\right] \tag{A.43}
\end{equation*}
$$

$$
\begin{equation*}
\operatorname{Pvec}(X)=\frac{1}{2}\left(X+X^{*}\right) \tag{A.44}
\end{equation*}
$$

From this follows that

$$
\begin{array}{|lll|}
\hline \operatorname{Pvec}(X)=\operatorname{vec}(X) & \text { if } & X=X^{*}  \tag{A.45}\\
\operatorname{Pvec}(X)=0 & \text { if } & X=-X^{*} \\
\hline
\end{array}
$$

Thus the range space of $P$ is spanned by vectors $\operatorname{vec}(X)$ with $X$ symmetric, and the null space of $P$ is spanned by vectors $\operatorname{vec}(X)$, with $X$ skew-symmetric. It will be clear from the above that the null spaces of $P$ and $Q_{v e c}$ are identical. Thus

$$
\begin{equation*}
N(P)=N\left(Q_{\text {vec }}\right) \tag{A.46}
\end{equation*}
$$

## Proof:

If $x \in N(P) \rightarrow P x=0 \rightarrow\left(Q_{t} \otimes Q_{t}\right) P x=0 \rightarrow Q_{v e c} x=0 \rightarrow x \in N\left(Q_{v e c}\right)$
If $x \in N\left(Q_{v e c}\right) \rightarrow\left(Q_{t} \otimes Q_{t}\right) P x=0 \rightarrow P x=0 \rightarrow x \in N(P)$

## A. 4 The Solution

Consider the linear model

$$
\begin{equation*}
E\{\underline{y}\}=A x, \quad D\{\underline{y}\}=Q_{y} \tag{A.47}
\end{equation*}
$$

Let $T=\left[T_{1}^{*} T_{2}^{*}\right]^{*}$ be a square and full rank matrix. Then with (A.47):

$$
E\left\{\left[\begin{array}{l}
T_{1} \underline{y}  \tag{A.48}\\
T_{2} \underline{y}
\end{array}\right]\right\}=\left[\begin{array}{l}
T_{1} A \\
T_{2} A
\end{array}\right] x, \quad D\left\{\left[\begin{array}{l}
T_{1} \underline{y} \\
T_{2} \underline{y}
\end{array}\right]\right\}=\left[\begin{array}{ll}
T_{1} Q_{y} T_{1}^{*} & T_{1} Q_{y} T_{2}^{*} \\
T_{2} Q_{y} T_{1}^{*} & T_{2} Q_{y} T_{2}^{*}
\end{array}\right]
$$

Now assume that

$$
\begin{equation*}
N\left(Q_{y}\right)=R\left(T_{2}^{*}\right), \quad R\left(T_{2}^{*}\right) \subset N\left(A^{*}\right) \tag{A.49}
\end{equation*}
$$

Then with (A.48)

$$
E\left\{\left[\begin{array}{l}
T_{1} \underline{y}  \tag{A.50}\\
T_{2} \underline{y}
\end{array}\right]\right\}=\left[\begin{array}{c}
T_{1} A x \\
0
\end{array}\right], \quad D\left\{\left[\begin{array}{l}
T_{1} \underline{y} \\
T_{2} \underline{y}
\end{array}\right]\right\}=\left[\begin{array}{cc}
T_{1} Q_{y} T_{1}^{*} & 0 \\
0 & 0
\end{array}\right]
$$

or

$$
\begin{equation*}
E\left\{T_{1} \underline{y}\right\}=T_{1} A x, \quad D\left\{T_{1} \underline{y}\right\}=T_{1} Q_{y} T_{1}^{*} \tag{A.51}
\end{equation*}
$$

The solution of this model reads:

$$
\begin{align*}
\hat{x} & =\left[A^{*} T_{1}^{*}\left(T_{1} Q_{y} T_{1}^{*}\right)^{-1} T_{1} A\right]^{-1} A^{*} T_{1}^{*}\left(T_{1} Q_{y} T_{1}^{*}\right)^{-1} T_{1} \underline{y}  \tag{A.52}\\
Q_{\hat{x}} & =\left[A^{*} T_{1}^{*}\left(T_{1} Q_{y} T_{1}^{*}\right)^{-1} T_{1} A\right]^{-1}
\end{align*}
$$

If we translate the above model to our situation, then

$$
\begin{equation*}
R\left(T_{1}^{*}\right)=R(P), \quad R\left(T_{2}^{*}\right)=N(P)=N\left(Q_{v e c}\right) \tag{A.53}
\end{equation*}
$$

Since $R\left(T_{1}^{*}\right)=R(P)$, we have

$$
\begin{equation*}
P=T_{1}^{*}\left(T_{1} T_{1}^{*}\right)^{-1} T_{1} \tag{A.54}
\end{equation*}
$$

Hence, with

$$
\begin{equation*}
Q_{v e c}=P Q_{t} \otimes Q_{t}=Q_{t} \otimes Q_{t} P \tag{A.55}
\end{equation*}
$$

we get

$$
\begin{equation*}
T_{1}^{*}\left(T_{1} T_{1}^{*}\right)^{-1} T_{1} Q_{v e c} T_{1}^{*}=Q_{t} \otimes Q_{t} T_{1}^{*} \tag{A.56}
\end{equation*}
$$

From this follows that

$$
\begin{equation*}
Q_{t}^{-1} \otimes Q_{t}^{-1} T_{1}^{*}\left(T_{1} T_{1}^{*}\right)^{-1}=T_{1}^{*}\left[T_{1} Q_{v e c} T_{1}^{*}\right]^{-1} \tag{A.57}
\end{equation*}
$$

or

$$
\begin{equation*}
Q_{t}^{-1} \otimes Q_{t}^{-1} T_{1}^{*}\left(T_{1} T_{1}^{*}\right)^{-1} T_{1}=T_{1}^{*}\left[T_{1} Q_{v e c} T_{1}^{*}\right]^{-1} T_{1} \tag{A.58}
\end{equation*}
$$

Hence

$$
\begin{equation*}
T_{1}^{*}\left[T_{1} Q_{v e c} T_{1}^{*}\right]^{-1} T_{1}=P Q_{t}^{-1} \otimes Q_{t}^{-1} P \tag{A.59}
\end{equation*}
$$
